OS/390

# MVS Programming: Callable Services for High-Level Languages

**Note**

Before using this information and the product it supports, be sure to read the general information under "Appendix. Notices" on page A-1.

**Eighth Edition, December 2000**

This is a major revision of GC28-1768-06.

This edition applies to Version 2 Release 10 of OS/390 (5647-A01) and to all subsequent releases and modifications until otherwise indicated in new editions

Order publications through your IBM representative or the IBM branch office serving your locality. Publications are not stocked at the address below.

IBM welcomes your comments. A form for readers' comments may be provided at the back of this publication, or you may address your comments to the following address:

## Part 1. Window Services

<b>Chapter 1. Introduction to Window Services</b> . . . . .	1-1
Structure of a Data Object . . . . .	1-1
What Does Window Services Provide? . . . . .	1-2
The Ways That Window Services Can Map an Object . . . . .	1-3
Access to Permanent Data Objects . . . . .	1-6
Access to Temporary Data Objects . . . . .	1-7
<b>Chapter 2. Using Window Services</b> . . . . .	2-1
Obtaining Access to a Data Object . . . . .	2-2
Identifying the Object . . . . .	2-2
Specifying the Object's Size . . . . .	2-3
Specifying the Type of Access . . . . .	2-3
Obtaining a Scroll Area . . . . .	2-3
Defining a View of a Data Object . . . . .	2-4
Identifying the Data Object . . . . .	2-4
Identifying a Window . . . . .	2-4
Defining the Disposition of a Window's Contents . . . . .	2-5
Defining the Expected Reference Pattern . . . . .	2-5
Identifying the Blocks You Want to View . . . . .	2-6
Extending the Size of a Data Object . . . . .	2-7
Defining Multiple Views of an Object . . . . .	2-7
Nonoverlapping Views . . . . .	2-7
Overlapping Views . . . . .	2-7
Saving Interim Changes to a Permanent Data Object . . . . .	2-8
Updating a Temporary Data Object . . . . .	2-8
Refreshing Changed Data . . . . .	2-9
Updating a Permanent Object on DASD . . . . .	2-9
When There is a Scroll Area . . . . .	2-10
When There is No Scroll Area . . . . .	2-10
Changing a View in a Window . . . . .	2-10
Terminating Access to a Data Object . . . . .	2-12
Handling Return Codes and Abnormal Terminations . . . . .	2-12
<b>Chapter 3. Window Services</b> . . . . .	3-1
CSREVV — View an Object and Sequentially Access It . . . . .	3-1
Abend Codes . . . . .	3-3
Return Codes and Reason Codes . . . . .	3-4
CSRIDAC — Request or Terminate Access to a Data Object . . . . .	3-5
Abend Codes . . . . .	3-8
Return Codes and Reason Codes . . . . .	3-8
CSRREFR — Refresh an Object . . . . .	3-10
Abend Codes . . . . .	3-11

Return Codes and Reason Codes . . . . .	3-11
CSRSAVE — Save Changes Made to a Permanent Object . . . . .	3-12
Abend Codes. . . . .	3-13
Return Codes and Reason Codes . . . . .	3-13
CSRSCOT — Save Object Changes in a Scroll Area . . . . .	3-15
Abend Codes. . . . .	3-16
Return Codes and Reason Codes . . . . .	3-16
CSRVIEW — View an Object . . . . .	3-17
Abend Codes. . . . .	3-20
Return Codes and Reason Codes . . . . .	3-20
<b>Chapter 4. Window Services Coding Examples.</b> . . . . .	4-1
ADA Example . . . . .	4-1
C/370 Example . . . . .	4-6
COBOL Example . . . . .	4-9
FORTRAN Example . . . . .	4-13
Pascal Example. . . . .	4-17
PL/I Example. . . . .	4-21

---

## Part 2. Reference Pattern Services

<b>Chapter 5. Introduction to Reference Pattern Services.</b> . . . . .	5-1
How Does the System Manage Data? . . . . .	5-1
An Example of How the System Manages Data in an Array . . . . .	5-2
What Pages Does the System Bring in When a Gap Exists? . . . . .	5-4
<b>Chapter 6. Using Reference Pattern Services</b> . . . . .	6-1
Defining the Reference Pattern for a Data Area. . . . .	6-1
Defining the Range of the Area . . . . .	6-1
Identifying the Direction of the Reference . . . . .	6-2
Defining the Reference Pattern. . . . .	6-2
Choosing the Number of Bytes on a Page Fault . . . . .	6-4
Examples of Using CSRIRP to Define a Reference Pattern . . . . .	6-5
Removing the Definition of the Reference Pattern. . . . .	6-6
Handling Return Codes . . . . .	6-7
<b>Chapter 7. Reference Pattern Services</b> . . . . .	7-1
CSRIRP — Define a Reference Pattern . . . . .	7-1
Return Codes and Reason Codes . . . . .	7-3
CSRRRP — Remove a Reference Pattern . . . . .	7-3
Return Codes and Reason Codes . . . . .	7-4
<b>Chapter 8. Reference Pattern Services Coding Examples.</b> . . . . .	8-1
C/370 Example . . . . .	8-1
COBOL Example . . . . .	8-4
FORTRAN Example. . . . .	8-8
Pascal Example. . . . .	8-11
PL/I Example. . . . .	8-13

---

## Part 3. Global Resource Serialization Latch Manager Services

<b>Chapter 9. Using the Latch Manager Services</b> . . . . .	9-1
Syntax and Linkage Conventions for Latch Manager Callable Services . . . . .	9-1
ISGLCRT — Create a Latch Set . . . . .	9-2
ABEND Codes. . . . .	9-3

Return Codes . . . . .	9-3
Examples of Calls to Latch Manager Services . . . . .	9-3
ISGLOBT — Obtain a Latch. . . . .	9-5
ABEND Codes. . . . .	9-7
Return Codes . . . . .	9-7
Example . . . . .	9-8
ISGLREL — Release a Latch . . . . .	9-8
ABEND Codes . . . . .	9-10
Return Codes . . . . .	9-10
Example . . . . .	9-11
ISGLPRG — Purge a Requestor from a Latch Set . . . . .	9-11
ABEND Codes . . . . .	9-12
Return Codes . . . . .	9-12
Example . . . . .	9-13
ISGLPBA — Purge a Group of Requestors from a Group of Latch Sets . . . . .	9-13
ABEND Codes . . . . .	9-15
Return Codes . . . . .	9-15

---

## Part 4. Resource Recovery Services (RRS)

<b>Chapter 10. Using Protected Resources . . . . .</b>	<b>10-1</b>
Resource Recovery Programs . . . . .	10-1
Two-Phase Commit Protocol . . . . .	10-2
Resource Recovery Process . . . . .	10-2
Requesting Resource Protection and Recovery . . . . .	10-4
Using Distributed Resource Recovery. . . . .	10-5
Application_Backout_UR (SRRBACK). . . . .	10-5
Description . . . . .	10-5
Application_Commit_UR (SRRCMIT) . . . . .	10-9

---

## Part 5. Other Callable Services

<b>Chapter 11. IEAAFFN — Assign Processor Affinity for Encryption or Decryption . . . . .</b>	<b>11-1</b>
Restrictions and Limitations . . . . .	11-2
Requirements. . . . .	11-2
Return Codes. . . . .	11-2
 <b>Chapter 12. CSRL16J — Transfer Control to Another Routine . . . . .</b>	 <b>12-1</b>
Defining the Entry Characteristics of the Target Routine . . . . .	12-1
Freeing Dynamic Storage Associated with the Caller . . . . .	12-2
Programming Requirements . . . . .	12-2
Restrictions . . . . .	12-5
Performance Implications . . . . .	12-5
Syntax Diagram . . . . .	12-5
C/370 Syntax. . . . .	12-5
PL/I Syntax . . . . .	12-6
Parameters . . . . .	12-6
Return Codes . . . . .	12-6
Example . . . . .	12-7
C/370 Example Program . . . . .	12-7
Assembler program for use with the C/370 example . . . . .	12-9
 <b>Chapter 13. CSRSI — System Information Service . . . . .</b>	 <b>13-1</b>
Description . . . . .	13-1

Environment . . . . .	13-1
Programming Requirements . . . . .	13-1
Restrictions . . . . .	13-1
Input Register Information . . . . .	13-1
Output Register Information . . . . .	13-2
Syntax . . . . .	13-2
Parameters . . . . .	13-2
Return Codes . . . . .	13-3
CSRSIC C/370 Header File . . . . .	13-4

## About This Book

Callable services are for use by any program coded in C, COBOL, FORTRAN, Pascal, or PL/I — this book refers to programs written in these languages as high-level language (HLL) programs. Callable services enable HLL programs to use specific MVS services by issuing program CALLs.

---

## Who Should Use This Book

This book is for programmers who code in C, COBOL, FORTRAN, Pascal, or PL/I and want to use the callable services that MVS provides.

---

## How to Use This Book

This book is one of the set of programming books for MVS. This set describes how to write programs in assembler language or high-level languages, such as C, FORTRAN, and COBOL. For more information about the content of this set of books, see *OS/390 Information Roadmap*.

---

## Where to Find More Information

Where necessary, this book references information in other books, using shortened versions of the book title. For complete titles and order numbers of the books for all products that are part of OS/390, see *OS/390 Information Roadmap*.

---

## Summary of Changes

| **Summary of Changes**  
| **for GC28-1768-07**  
| **as Updated December 2000**

| This book contains information previously presented in GC28-1768-06 which  
| supports OS/390 Version 2 Release 7.

| **New Information**

| Application\_Backout\_UR and Application\_Commit\_UR cannot be used with URs in  
| local transaction mode.

| This book includes terminology, maintenance, and editorial changes. Technical  
| changes or additions to the text and illustrations are indicated by a vertical line to  
| the left of the change.

| **Summary of Changes**  
| **for GC28-1768-06**  
| **as Updated June, 1999**  
| **online only for SK2T-6700-13**

| The book contains information previously presented in GC28-1768-05, which  
| supports OS/390 Version 2 Release 7.

| **New Information**

| This book now describes the new callable service CSRSI which is used to retrieve  
| system information.

| This revision reflects the deletion, addition, or modification of information to support  
| miscellaneous maintenance items. A vertical bar in the left margin indicates  
| changes to the text and illustrations.

| **Summary of Changes**  
| **for GC28-1768-05**  
| **OS/390 Version 2 Release 7**

| The book contains information previously presented in GC28-1768-04, which  
| supports OS/390 Version 2 Release 6.

| This book includes terminology, maintenance, and editorial changes. Technical  
| changes or additions to the text and illustrations are indicated by a vertical line to  
| the left of the change.

| **Summary of Changes**  
| **for GC28-1768-04**  
| **OS/390 Version 2 Release 6**

| The book contains information previously presented in GC28-1768-03, which  
| supports OS/390 Version 2 Release 4.

This book includes terminology, maintenance, and editorial changes. Technical changes or additions to the text and illustrations are indicated by a vertical line to the left of the change.

**Summary of Changes  
for GC28-1768-03  
OS/390 Version 2 Release 4**

The book contains information previously presented in GC28-1768-02, which supports OS/390 Version 1 Release 3.

This book includes terminology, maintenance, and editorial changes. Technical changes or additions to the text and illustrations are indicated by a vertical line to the left of the change.

**Summary of Changes  
for GC28-1768-02  
as Updated June, 1997  
online only for SK2T-6700-05**

The following changes appear only in the online version of this publication.

**New Information**

- This book now describes the following new callable services:  
Application\_Commit\_UR  
Application\_Backout\_UR

An application uses these services to commit or back out changes to a set of resources represented by a unit of recovery (UR).

These services require a resource manager that works with RRS to provide recovery for protected resources.

A pair of vertical dots ( : ) in the left margin indicates changes to the text and illustrations.

This revision reflects the deletion, addition, or modification of information to support miscellaneous maintenance items.

**Summary of Changes  
for GC28-1768-02  
OS/390 Version 1 Release 3**

The book contains information previously presented in GC28-1768-01, which supports OS/390 Version 1 Release 2.

**New Information**

- New latch manager service request ISGLPBA that purges a group of requestors from a group of latch sets

This book includes terminology, maintenance, and editorial changes. Technical changes or additions to the text and illustrations are indicated by a vertical line to the left of the change.

**Summary of Changes  
for GC28-1768-01  
OS/390 Version 1 Release 2**

This book contains information previously presented in *OS/390 MVS Programming: Callable Services for High-Level Languages*, GC28-1868-00, which supports OS/390 Release 1.

This book includes terminology, maintenance, and editorial changes. Technical changes or additions to the text and illustrations are indicated by a vertical line to the left of the change.

**Summary of Changes  
for GC28-1768-00  
OS/390 Version 1 Release 1**

This book contains information previously presented in *MVS/ESA Programming: Callable Services for High Level Languages*, GC28-1464, which supports MVS/ESA System Product Version 5.

This book includes terminology, maintenance, and editorial changes. Technical changes or additions to the text and illustrations are indicated by a vertical line to the left of the change.

## Chapter 1. Introduction to Window Services

Window services allow HLL programs to:

- Read or update an existing permanent data object
- Create and save a new permanent data object
- Create and use a temporary data object

Window services enable your program to access data objects without your program performing any input or output (I/O) operations. All your program needs to do is issue a CALL to the appropriate service program. The service program performs any I/O operations that are required to make the data object available to your program. When you want to update or save a data object, window services again perform any required I/O operations.

### Permanent Data Objects

A **permanent data object** is a virtual storage access method (VSAM) linear data set that resides on DASD. (This type of data set is also called a data-in-virtual object.) You can read data from an existing permanent object and also update the content of the object. You can create a new permanent object and when you are finished, save it on DASD. Because you can save this type of object on DASD, window services calls it a **permanent object**. Window services can handle very large permanent objects that contain as many as 4 gigabytes (four billion bytes).

**Note:** Installations whose FORTRAN programs used data-in-virtual objects prior to MVS/SP 3.1.0 had to write an Assembler language interface program to allow the FORTRAN program to invoke the data-in-virtual program. Window services eliminates the need for this interface program.

### Temporary Data Objects

A **temporary data object** is an area of expanded storage that window services provides for your program. You can use this storage to hold temporary data, such as intermediate results of a computation, instead of using a DASD workfile. Or you might use the storage area as a temporary buffer for data that your program generates or obtains from some other source. When you finish using the storage area, window services deletes it. Because you cannot save the storage area, window services calls it a temporary object. Window services can handle very large temporary objects that contain as many as 16 terabytes (16 trillion bytes).

---

## Structure of a Data Object

Think of a data object as a contiguous string of bytes organized into blocks, each 4096 bytes long. The first block contains bytes 0 to 4095 of the object, the second block contains bytes 4096 to 8191, and so forth.

Your program references data in the object by identifying the block or blocks that contain the desired data. Window services makes the blocks available to your program by mapping a **window** in your program storage to the blocks. A window is a storage area that your program provides and makes known to window services. **Mapping** the window to the blocks means that window services makes the data from those blocks available in the window when you reference the data. You can map a window to all or part of a data object depending on the size of the object and

the size of the window. You can examine or change data that is in the window by using the same instructions that you use to examine or change any other data in your program storage.

The following figure shows the structure of a data object and shows a window mapped to two of the object's blocks.

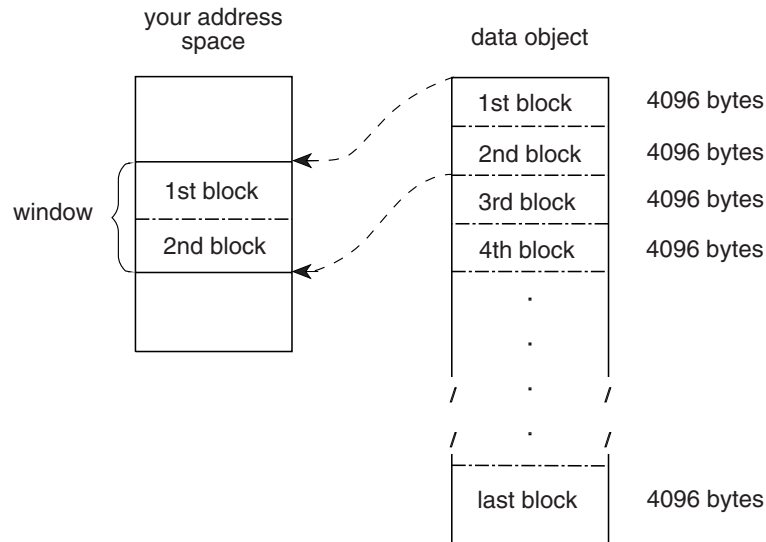

Figure 1-1. Structure of a Data Object

---

## What Does Window Services Provide?

Window services allows you to view and manipulate data objects in a number of ways. You can have access to one or more data objects at the same time. You can also define multiple windows for a given data object. You can then view a different part of the object through each window. Before you can access any data object, you must request access from window services.

When you request access to a permanent data object, you must indicate whether you want a scroll area. A **scroll area** is an area of expanded storage that window services obtains and maps to the permanent data object. You can think of the permanent object as being available in the scroll area. When you request a view of the object, window services maps the window to the scroll area. If you do not request a scroll area, window services maps the window directly to the object on DASD.

A scroll area enables you to save interim changes to a permanent object without changing the object on DASD. Also, when your program accesses a permanent object through a scroll area, your program might attain better performance than it would if the object were accessed directly on DASD.

When you request a temporary object, window services provides an area of expanded storage. This area of expanded storage is the temporary data object. When you request a view of the object, window services maps the window to the temporary object. Window services initializes a temporary object to binary zeroes.

**Notes:**

1. Window services does not transfer data from the object on DASD, from the scroll area, or from the temporary object until your program references the data. Then window services transfers those blocks.
2. The expanded storage that window services uses for a scroll area or for a temporary object is called a **hiperspace**. A hiperspace is a range of contiguous virtual storage addresses that a program can indirectly access through a window in the program's virtual storage. Window services uses as many hiperspaces as needed to contain the data object.

## The Ways That Window Services Can Map an Object

Window services can map a data object a number of ways. The following examples show how window services can:

- Map a permanent object that has no scroll area
- Map a permanent object that has a scroll area
- Map a temporary object
- Map an object to multiple windows
- Map multiple objects

### Example 1 — Mapping a Permanent Object that has no Scroll Area

If a permanent object has no scroll area, window services maps the object from DASD directly to your window. In this example, your window provides a view of the first and second blocks of an object.

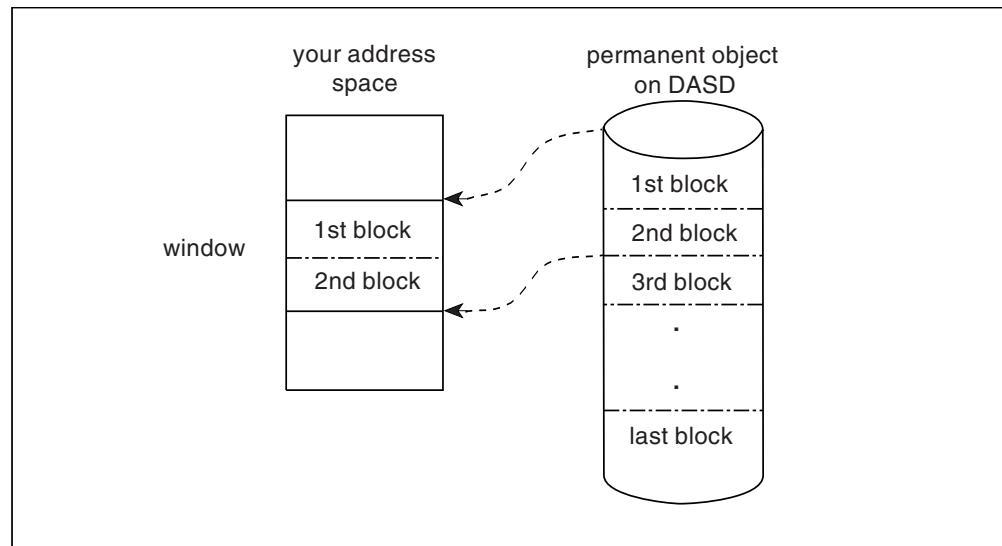

Figure 1-2. Mapping a Permanent Object That Has No Scroll Area

### Example 2 — Mapping a Permanent Object that has a Scroll Area

If the object has a scroll area, window services maps the object from DASD to the scroll area. Window services then maps the blocks that you wish to view from the scroll area to your window. In this example, your window provides a view of the third and fourth blocks of an object.

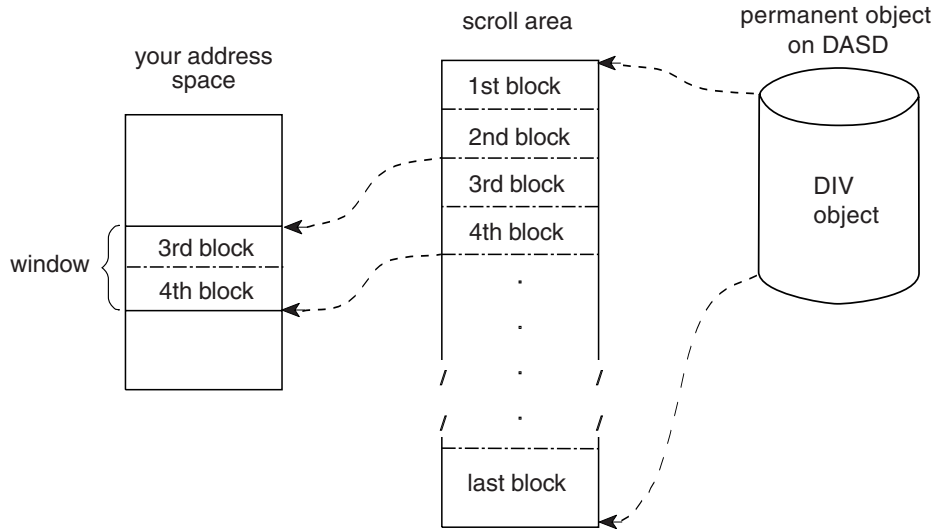

Figure 1-3. Mapping a Permanent Object That Has a Scroll Area

### Example 3 — Mapping a Temporary Object

Window services uses a hiperspace as a temporary object. In this example, your window provides a view of the first and second blocks of a temporary object.

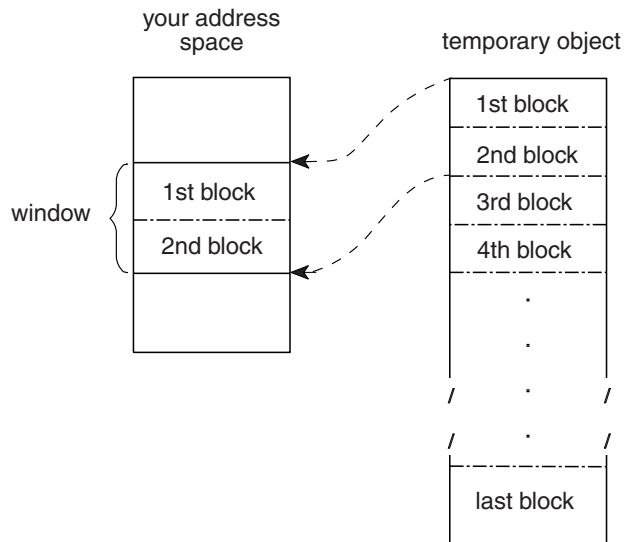

Figure 1-4. Mapping a Temporary Object

### Example 4 — Mapping Multiple Windows to an Object

Window services can map multiple windows to the same object. In this example, one window provides a view of the second and third blocks of an object, and a second window provides a view of the last block.

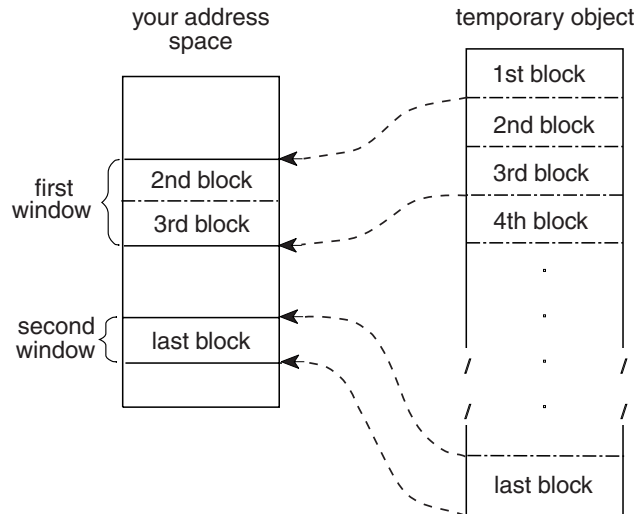

Figure 1-5. Mapping an Object to Multiple Windows

### Example 5 — Mapping Multiple Objects

Window services can map windows in the same address space to multiple objects. The objects can be temporary objects, permanent objects, or a combination of temporary and permanent objects. In this example, one window provides a view of the second block of a temporary object, and a second window provides a view of the fourth and fifth blocks of a permanent object.

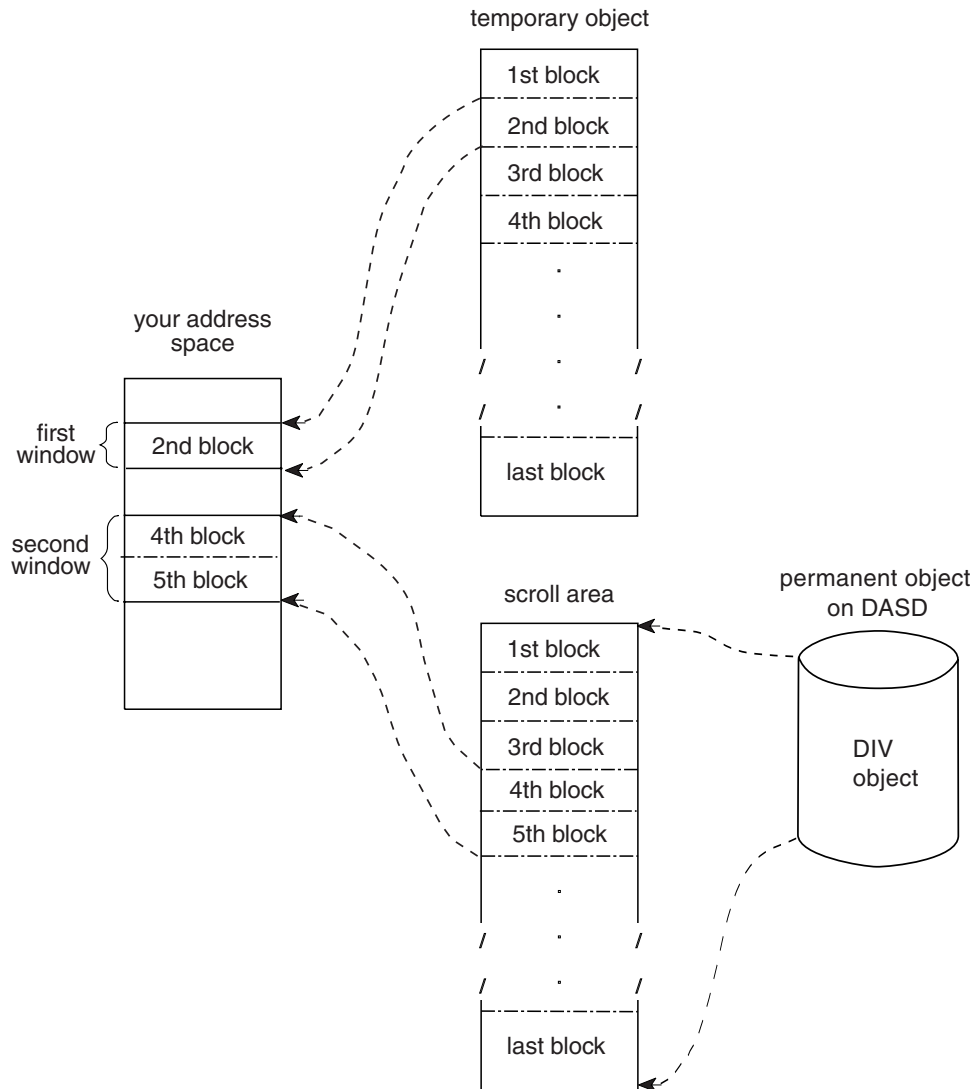

Figure 1-6. Mapping Multiple Objects

## Access to Permanent Data Objects

When you have access to a permanent data object, you can:

- **View the object through one or more windows** — Depending on the object size and the window size, a single window can view all or part of a permanent object. If you define multiple windows, each window can view a different part of the object. For example, one window might view the first block of the permanent object and another window might view the second block. You can also have several windows view the same part of the object or have views in multiple windows overlap. For example, one window might view the first and second blocks of a data object while another window views the second and third blocks.
- **Change data that appears in a window** — You can examine or change data that is in a window by using the same instructions you use to examine or change any other data in your program's storage. These changes do not alter the object on DASD or in the scroll area.

- **Save interim changes in a scroll area** — After changing data in a window, you can have window services save the changed blocks in a scroll area, if you have requested one. Window services replaces blocks in the scroll area with corresponding changed blocks from the window. Saving changes in the scroll area does not alter the object on DASD or alter data in the window.
- **Refresh a window or the scroll area** — After you change data in a window or save changes in the scroll area, you may discover that you no longer need those changes. In that case, you can have window services refresh the changed data. To refresh the window or the scroll area, window services replaces changed data with data from the object as it appears on DASD.
- **Replace the view in a window** — After you finish using data that is in a window, you can have window services replace the view in the window with a different view of the object. For example, if you are viewing the third, fourth, and fifth blocks of an object and are finished with those blocks, you might have window services replace that view with a view of the sixth, seventh, and eighth blocks.
- **Update the object on DASD** — If you have changes available in a window or in the scroll area, you can save the changes on DASD. Window services replaces blocks on DASD with corresponding changed blocks from the window and the scroll area. Updating an object on DASD does not alter data in the window or in the scroll area.

## Access to Temporary Data Objects

When you have access to a temporary data object, you can:

- **View the object through one or more windows** — Depending on the object size and the window size, a single window can view all or part of a temporary object. If you define multiple windows, each window can view a different part of the object. For example, one window might view the first block of the temporary object and another window might view the second block. Unlike a permanent object, however, you cannot define multiple windows that have overlapping views of a temporary object.
- **Change data that appears in a window** — This function is the same for a temporary object as it is for a permanent object: you can examine or change data that is in a window by using the same instructions you use to examine or change any other data in your address space.
- **Update the temporary object** — After you have changed data in a window, you can have window services update the object with those changes. Window services replaces blocks in the object with corresponding changed blocks from the window. The data in the window remains as it was.
- **Refresh a window or the object** — After you change data in a window or save changes in the object, you may discover that you no longer need those changes. In that case, you can have window services refresh the changed data. To refresh the window or the object, window services replaces changed data with binary zeroes.
- **Replace the view in a window** — After you finish using data that is in a window, you can have window services replace the view in the window with a different view of the object. For example, if you are viewing the third, fourth, and fifth blocks of an object and are finished with those blocks, you might have window services replace that view with a view of the sixth, seventh, and eighth blocks.

---

## Chapter 2. Using Window Services

To use, create, or update a data object, you call a series of programs that window services provides. These programs enable you to:

- Access an existing object, create and save a new permanent object, or create a temporary object
- Obtain a scroll area where you can make interim changes to a permanent object
- Define windows and establish views of an object in those windows
- Change or terminate the view in a window
- Update a scroll area or a temporary object with changes you have made in a window
- Refresh changes that you no longer need in a window or a scroll area
- Update a permanent object on DASD with changes that are in a window or a scroll area
- Terminate access to an object

The window services programs that you call and the sequence in which you call them depends on your use of the data object.

The first step in using any data object is to gain access to the object. To gain access, call CSRIDAC. The object can be an existing permanent object, or a new permanent or temporary object you want to create. For a permanent object, you can request an optional scroll area. A scroll area enables you to make interim changes to an object's data without affecting the data on DASD. When CSRIDAC grants access, it provides an object identifier that identifies the object. Use that identifier to identify the object when you request other services from window services.

After obtaining access to an object, define one or more windows and establish views of the object in those windows. To establish a view of an object, tell window services which blocks you want to view and in which windows. You can view multiple objects and multiple parts of each object at the same time. To define windows and establish views, call CSRVIEW or CSREVV. After establishing a view, you can examine or change data that is in the window using the same instructions you use to examine or change other data in your program's storage.

After making changes to the part of an object that is in a window, you will probably want to save those changes. How you save changes depends on whether the object is permanent, is temporary, or has a scroll area.

If the object is permanent and has a scroll area, you can save changes in the scroll area without affecting the object on DASD. Later, you can update the object on DASD with changes saved in the scroll area. If the object is permanent and has no scroll area, you can update it on DASD with changes that are in a window. If the object is temporary, you can update it with changes that are in a window. To update an object on DASD, call CSRSAVE. To update a temporary object or a scroll area, call CSRSCOT.

After making changes in a window and possibly saving them in a scroll area or using them to update a temporary object, you might decide that you no longer need those changes. In this case, you can refresh the changed blocks. After refreshing a block of a permanent object or a scroll area to which a window is mapped, the refreshed block contains the same data that the corresponding block contains on

DASD. After refreshing a block of a temporary object to which a window is mapped, the block contains binary zeroes. To refresh a changed block, call CSRREFR.

After finishing with a view in a window, you can use the same window to view a different part of the object or to view a different object. Before changing the view in a window, you must terminate the current view. If you plan to view a different part of the same object, terminate the current view by calling CSRVIEW. If you plan to view a different object or will not reuse the window, you can terminate the view by calling CSRIDAC.

When you finish using a data object, terminate access to the object by calling CSRIDAC.

The following restrictions apply to using window services:

1. When you attach a new task, you cannot pass ownership of a mapped virtual storage window to the new task. That is, you cannot use the ATTACH or ATTACHX keywords GSPV and GSPL to pass the mapped virtual storage.
2. While your program is in cross-memory mode, your program cannot invoke data-in-virtual services; however, your program can reference and update data in a mapped virtual storage window.
3. The task that obtains the ID (through DIV IDENTIFY) is the only one that can issue other DIV services for that ID.
4. When you identify a data-in-virtual object using the IDENTIFY service, you cannot request a checkpoint until you invoke the corresponding UNIDENTIFY service.

This chapter explains how to do the previously described functions and contains the following topics:

- “Defining Multiple Views of an Object” on page 2-7
- “Saving Interim Changes to a Permanent Data Object” on page 2-8
- “Updating a Temporary Data Object” on page 2-8
- “Refreshing Changed Data” on page 2-9
- “Updating a Permanent Object on DASD” on page 2-9
- “Changing a View in a Window” on page 2-10
- “Terminating Access to a Data Object” on page 2-12
- “Handling Return Codes and Abnormal Terminations” on page 2-12.

---

## Obtaining Access to a Data Object

To obtain access to a permanent or temporary data object, call CSRIDAC. Indicate that you want to access an object by specifying BEGIN as the value for *op\_type*. For a description of the CSRIDAC parameters and return codes, see “CSRIDAC — Request or Terminate Access to a Data Object” on page 3-5.

## Identifying the Object

You must identify the data object you wish to access. How you identify the object depends on whether the object is permanent or temporary.

### Permanent Object

For a permanent object, *object\_name* and *object\_type* work together. For *object\_name* you have a choice: specify either the data set name of the object or the DDNAME to which the object is allocated. The *object\_type* parameter must then indicate whether *object\_name* is a DDNAME or a data set name:

- If *object\_name* is a DDNAME, specify DDNAME as the value for *object\_type*.
- If *object\_name* is a data set name, specify DSNAME as the value for *object\_type*.

If you specify DSNAME for *object\_type*, indicate whether the object already exists or whether window services is to create it:

- If the object already exists, specify OLD as the value for *object\_state*.
- If window services is to create the object, specify NEW as the value for *object\_state*.

#### Requirement for NEW objects

If you specify NEW as the value for *object\_state*, your system must include MVS/Data Facility Product. (MVS/DFP) 3.1.0 and SMS must be active.

### Temporary Object

To identify a temporary object, specify TEMPSPACE as the value for *object\_type*. Window services assumes that a temporary object is new and ignores the value that you specify for *object\_state*.

## Specifying the Object's Size

If the object is permanent and new or is temporary, you must tell window services the size of the object. You specify object size through the *object\_size* parameter. The size specified becomes the maximum size that window services will allow for that object. You express the size as a number of 4096-byte blocks. If the number of bytes in the object is not an exact multiple of 4096, round *object\_size* to the next whole number. For example:

- If the object size is to be less than 4097 bytes, specify 1.
- If the object size is 5000 bytes, specify 2.
- If the object size is 410,000 bytes, specify 101.

## Specifying the Type of Access

For an existing (OLD) permanent object, you must specify how you intend to access the object. You specify your intentions through the *access\_mode* parameter:

- If you intend to only read the object, specify READ for *access\_mode*.
- If you intend to update the object, specify UPDATE for *access\_mode*.

For a new permanent object and for a temporary object, window services assumes you will update the object and ignores the value you specify for *access\_mode*.

## Obtaining a Scroll Area

A scroll area is storage that window services provides for your use. This storage is outside your program's storage area and is accessible only through window services.

For a permanent object, a scroll area is optional. A scroll area allows you to make interim changes to a permanent object without altering the object on DASD. Later, if you want, you can update the object on DASD with the interim changes. A scroll area might also improve performance when your program accesses a permanent object.

For a temporary object, the scroll area is the object. Therefore, for a temporary object, a scroll area is required.

To indicate whether you want a scroll area, provide the appropriate value for *scroll\_area*:

- To request a scroll area, supply a value of YES. YES is required for a temporary object.
- To indicate you do not want a scroll area, supply a value of NO.

---

## Defining a View of a Data Object

To view all or part of a data object, you must provide window services with information about the object and how you want to view it. You must provide window services with the following information:

- The object identifier
- Where the window is in your address space
- Window disposition — that is, whether window services is to initialize the window the first time you reference data in the window
- Whether you intend to reference blocks of data sequentially or randomly
- The blocks of data that you want to view
- Whether you want to extend the size of the object

To define a view of a data object, call `CSRVIEW` or `CSREVIEW`. Whether you use `CSRVIEW` or `CSREVIEW` depends on how you plan to reference the data. “Defining the Expected Reference Pattern” on page 2-5 describes the differences between the two services. Specify `BEGIN` on `CSRVIEW` or `CSREVIEW` as the type of operation. For descriptions of the `CALL` syntax and return codes from `CSRVIEW` or `CSREVIEW`, see “`CSRVIEW` — View an Object” on page 3-17 or “`CSREVIEW` — View an Object and Sequentially Access It” on page 3-1.

## Identifying the Data Object

To identify the object you want to view, specify the object identifier as the value for *object\_id*. Use the same value `CSRIDAC` returned in *object\_id* when you requested access to the object.

## Identifying a Window

You must identify the window through which you will view the object. The window is a virtual storage area in your address space. You are responsible for obtaining the storage, which must meet the following requirements:

- The storage must not be page fixed.
- Pages in the window must not be page loaded (must not be loaded by the `PGLOAD` macro).
- The storage must start on a 4K boundary and must be a multiple of 4096 bytes in length.

To identify the window, use the *window\_name* parameter. The value supplied for *window\_name* must be the symbolic name you assigned to the window storage area in your program.

Defining a window in this way provides one window through which you can view the object. To define multiple windows that provide simultaneous views of different parts of the object, see “Defining Multiple Views of an Object” on page 2-7.

## Defining the Disposition of a Window's Contents

You must specify whether window services is to replace or retain the window contents. You do this by selecting either the replace or retain option. This option determines how window services handles the data that is in the window the first time you reference the data. You select the option by supplying a value of REPLACE or RETAIN for *disposition*.

### Replace Option

If you specify the replace option, the first time you reference a block to which a window is mapped, window services replaces the data in the window with corresponding data from the object. For example, assume you have requested a view of the first block of a permanent object and have specified the replace option. The first time you reference the window, window services replaces the data in the window with the first 4096 bytes (the first block) from the object.

If you have selected the replace option and then call CSRSAVE to update a permanent object, or call CSRSCOT to update a scroll area, or call CSRSCOT to update a temporary object, window services updates only the specified blocks that have changed and to which a window is mapped.

Select the replace option when you want to examine, use, or change data that is currently in an object.

### Retain Option

If you select the retain option, window services retains data that is in the window. When you reference a block in the window the first time, the block contains the same data it contained before the reference.

When you select the retain option, window services considers all of the data in the window as changed. Therefore, if you call CSRSCOT to update a scroll area or a temporary object, or call CSRSAVE to update a permanent object, window services updates all of the specified blocks to which a window or scroll area are mapped.

Select the retain option when you want to replace data in an object without regard for the data that it currently contains. You also use the retain option when you want to initialize a new object.

## Defining the Expected Reference Pattern

You must tell window services whether you intend to reference the blocks of an object sequentially or randomly. An intention to access randomly tells window services to bring one block (4096 bytes) of data into the window at a time. An intention to access sequentially tells window services to read more than one block into your window at one time. The performance gain is in having blocks of data already in central storage at the time the program needs to reference them. You specify the intent on either CSRVIEW or CSREVIEW, two services that differ on how to specify sequential access.

- CSRVIEW allows you a choice between random or sequential access.

If you specify **random**, when you reference data that is not in your window, window services brings in one block — the one that contains the data your program references.

If you specify **sequential**, when you reference data that is not in your window, window services transfers up to 16 blocks — the one that contains the data your program requests, plus the next 15 consecutive blocks. The number of consecutive blocks varies, depending on the size of the window and availability of central storage. Use CSRVIEW if one of the following is true:

- You are going to access randomly.
- You are going to access sequentially, and you are satisfied with a maximum of 16 blocks coming into the window at a time.
- CSREVV is for sequential access only. It allows you to specify the maximum number of consecutive blocks that window services brings into the window at one time. The number ranges from one block through 256 blocks. Use CSREVV if you want fewer than 16 blocks or more than 16 blocks at one time. Programs that benefit from having more than 16 blocks come into a window at one time reference data areas that are greater than one megabyte.

To specify the reference pattern on CSRVIEW, supply a value of SEQ or RANDOM for *usage*.

To specify the reference pattern on CSREVV, supply a number from 0 through 255 for *pfcount*. *pfcount* represents the number of blocks window services will bring into the window, in addition to the one that it always brings in.

Note that window services brings in multiple pages differently depending on whether your object is permanent or temporary and whether the system has had to move pages of your data from central storage to make those pages of central available for other programs. The rule is that SEQ on CSRVIEW and *pfcount* on CSREVV apply to:

- A **permanent object** when movement is from the object on DASD to central storage
- A **temporary object** when your program has scrolled the data out and references it again

SEQ and *pfcount* do not apply after the system has had to move data (either changed or unchanged) to auxiliary or expanded storage, and your program again references it, requiring the system to bring the data back into central storage.

End the view, whether established with CSRVIEW or CSREVV, with CSRVIEW END.

## Identifying the Blocks You Want to View

To identify the blocks of data you want to view, use *offset* and *span*. The values you assign to *offset* and *span*, together, define a contiguous string of blocks that you want to view:

- The value assigned to *offset* specifies the relative block at which to start the view. An offset of 0 means the first block; an offset of 1 means the second block; an offset of 2 means the third block, and so forth.
- The value assigned to *span* specifies the number of blocks to view. A span of 1 means one block; a span of 2 means two blocks, and so forth. A span of 0 has special meaning: it means the view is to start at the specified offset and extend until the currently defined end of the object.

The following table shows examples of several *offset* and *span* combinations and the resulting view in the window.

Offset	Span	Resulting view in the window
0	0	view the entire object
0	1	view the first block only
1	0	view the second block through the last block
1	1	view the second block only

Offset	Span	Resulting view in the window
2	2	view the third and fourth blocks only

## Extending the Size of a Data Object

You can use *offset* and *span* to extend the size of an object up to the previously defined maximum size for the object. You can extend the size of either permanent objects or temporary objects. For objects created through CSRIDAC, the value assigned to *object\_size* defines the maximum allowable size. When you call CSRIDAC to gain access to an object, CSRIDAC returns a value in *high\_offset* that defines the current size of the object.

For example, assume you have access to a permanent object whose maximum allowable size is four 4096-byte blocks. The object is currently two blocks long. If you define a window and specify an offset of 1 and a span of 2, the window contains a view of the second block and a view of a third block, which does not yet exist in the permanent object. When you reference the window, the content of the second block, as seen in the window, depends on the disposition you selected, replace or retain. The third block, as seen in the window, initially contains binary zeroes. If you later call CSRSAVE to update the permanent object with changes from the window, window services extends the size of the permanent object to three blocks by appending the new block of data to the object.

---

## Defining Multiple Views of an Object

You might need to view different parts of an object at the same time. For a permanent object, you can define windows that have nonoverlapping views as well as windows that have overlapping views. For a temporary object, you can define windows that have only nonoverlapping views.

- A nonoverlapping view means that no two windows view the same block of the object. For example, a view is nonoverlapping when one window views the first and second blocks of an object and another window views the ninth and tenth blocks of the same object. Neither window views a common block.
- An overlapping view means that two or more windows view the same block of the object. For example, the view overlaps when the second window in the previous example views the second and third blocks. Both windows view a common block, the second block.

## Nonoverlapping Views

To define multiple windows that have a nonoverlapping view, call CSRIDAC once to obtain the object identifier. Then call CSRVIEW or CSREVV once to define each window. On each call, specify the value BEGIN for *operation\_type*, the same object identifier for *object\_id*, and a different value for *window\_name*. Define each window's view by specifying values for *offset* and *span* that create windows with nonoverlapping views.

## Overlapping Views

To define multiple windows that have an overlapping view of a permanent object, define each window as though it were viewing a different object. That is, define each window under a different object identifier. To obtain the object identifiers, call CSRIDAC once for each identifier you need. Only one of the calls to CSRIDAC can specify an access mode of UPDATE. Other calls to CSRIDAC must specify an access mode of READ.

After calling CSRIDAC, call CSRVIEW or CSREVIEW once to define each window. On each call, specify the value BEGIN for the operation type, a different object identifier for *object\_id*, and a different value for *window\_name*. Define each window's view by specifying values for *offset* and *span* that create windows with the required overlapping views.

---

## Saving Interim Changes to a Permanent Data Object

Window services allows you to save interim changes you make to a permanent object. You must have previously requested a scroll area for the object, however. You request a scroll area when you call CSRIDAC to gain access to the object. Window services saves changes by replacing blocks in the scroll area with corresponding changed blocks from a window. Saving changes in the scroll area does not alter the object on DASD.

After you have a view of the object and have made changes in the window, you can save those changes in the scroll area. To save changes in the scroll area, call CSRSCOT. For a description of the CSRSCOT parameters and return codes, see "CSRSCOT — Save Object Changes in a Scroll Area" on page 3-15.

To identify the object, you must supply an object identifier for *object\_id*. The value supplied for *object\_id* must be the same value CSRIDAC returned in *object\_id* when you requested access to the object.

To identify the blocks in the object that you want to update, use *offset* and *span*. The values assigned to *offset* and *span*, together, define a contiguous string of blocks in the object:

- The value assigned to *offset* specifies the relative block at which to start. An offset of 0 means the first block; an offset of 1 means the second block; an offset of 2 means the third block, and so forth.
- The value assigned to *span* specifies the number of blocks to save. A span of 1 means one block; a span of 2 means two blocks, and so forth. A span of 0 has special meaning: it requests that window services save all changed blocks to which a window is mapped.

Window services replaces each block within the range specified by *offset* and *span* providing the block has changed and a window is mapped to the block.

---

## Updating a Temporary Data Object

After making changes in a window to a temporary object, you can update the object with those changes. You must identify the object and must specify the range of blocks that you want to update. To be updated, a block must be mapped to a window and must contain changes in the window. Window services replaces each block within the specified range with the corresponding changed block from a window.

To update a temporary object, call CSRSCOT. For a description of the CSRSCOT parameters and return codes, see "CSRSCOT — Save Object Changes in a Scroll Area" on page 3-15.

To identify the object, you must supply an object identifier for *object\_id*. The value you supply for *object\_id* must be the same value CSRIDAC returned in *object\_id* when you requested access to the object.

To identify the blocks in the object that you want to update, use *offset* and *span*. The values assigned to *offset* and *span*, together, define a contiguous string of blocks in the object:

- The value assigned to *offset* specifies the relative block at which to start. An offset of 0 means the first block; an offset of 1 means the second block; an offset of 2 means the third block, and so forth.
- The value assigned to *span* specifies the number of blocks to save. A span of 1 means one block; a span of 2 means two blocks, and so forth. A span of 0 has special meaning: it requests that window services update all changed blocks to which a window is mapped.

Window services replaces each block within the range specified by *offset* and *span* providing the block has changed and a window is mapped to the block.

---

## Refreshing Changed Data

You can refresh blocks that are mapped to either a temporary object or to a permanent object. You must identify the object and specify the range of blocks you want to refresh. When you refresh blocks mapped to a temporary object, window services replaces, with binary zeros, all changed blocks that are mapped to the window. When you refresh blocks mapped to a permanent object, window services replaces specified changed blocks in a window or in the scroll area with corresponding blocks from the object on DASD.

To refresh an object, call CSRREFR. For a description of CSRREFR parameters and return codes, see “CSRREFR — Refresh an Object” on page 3-10.

To identify the object, you must supply an object identifier for *object\_id*. The value supplied for *object\_id* must be the same value CSRIDAC returned in *object\_id* when you requested access to the object.

To identify the blocks of the object that you want to refresh, use *offset* and *span*. The values assigned to *offset* and *span*, together, define a contiguous string of blocks in the object:

- The value assigned to *offset* specifies the relative block at which to start. An offset of 0 means the first block; an offset of 1 means the second block; an offset of 2 means the third block, and so forth.
- The value assigned to *span* specifies the number of blocks to save. A span of 1 means one block; a span of 2 means two blocks, and so forth. A span of 0 has special meaning: it requests that window services refresh all changed blocks to which a window is mapped, or that have been saved in a scroll area.

Window services refreshes each block within the range specified by *offset* and *span* providing the block has changed and a window or a scroll area is mapped to the block. At the completion of the refresh operation, blocks from a permanent object that have been refreshed appear the same as the corresponding blocks on DASD. Refreshed blocks from a temporary object contain binary zeroes.

---

## Updating a Permanent Object on DASD

You can update a permanent object on DASD with changes that appear in a window or in the object’s scroll area. You must identify the object and specify the range of blocks that you want to update.

To update an object, call CSRSAVE. For a description of the CSRSAVE parameters and return codes, see “CSRSAVE — Save Changes Made to a Permanent Object” on page 3-12.

To identify the object, you must supply an object identifier for *object\_id*. The value you provide for *object\_id* must be the same value CSRIDAC returned when you requested access to the object.

To identify the blocks of the object that you want to update, use *offset* and *span*. The values assigned to *offset* and *span*, together, define a contiguous string of blocks in the object:

- The value assigned to *offset* specifies the relative block at which to start. An offset of 0 means the first block; an offset of 1 means the second block; an offset of 2 means the third block, and so forth.
- The value assigned to *span* specifies the number of blocks to save. A span of 1 means one block; a span of 2 means two blocks, and so forth. A span of 0 has special meaning: it requests that window services update all changed blocks to which a window is mapped, or have been saved in the scroll area.

## When There is a Scroll Area

When the object has a scroll area, window services first updates blocks in the scroll area with corresponding blocks from windows. To be updated, a scroll area block must be within the specified range, a window must be mapped to the block, and the window must contain changes. Window services next updates blocks on DASD with corresponding blocks from the scroll area. To be updated, a DASD block must be within the specified range and have changes in the scroll area. Blocks in the window remain unchanged.

## When There is No Scroll Area

When there is no scroll area, window services updates blocks of the object on DASD with corresponding blocks from a window. To be updated, a DASD block must be within the specified range, mapped to a window, and have changes in the window. Blocks in the window remain unchanged.

---

## Changing a View in a Window

To change the view in a window so you can view a different part of the same object or view a different object, you must first terminate the current view. To terminate the view, whether the view was mapped by CSRVIEW or CSREVIEW, call CSRVIEW and supply a value of END for *operation\_type*. You must also identify the object, identify the window, identify the blocks you are currently viewing, and specify a disposition for the data that is in the window. For a description of CSRVIEW parameters and return codes, see “CSRVIEW — View an Object” on page 3-17.

To identify the object, supply an object identifier for *object\_id*. The value supplied for *object\_id* must be the value you supplied when you established the view.

To identify the window, supply the window name for *window\_name*. The value supplied for *window\_name* must be the same value you supplied when you established the view.

To identify the blocks you are currently viewing, supply values for *offset* and *span*. The values you supply must be the same values you supplied for *offset* and *span* when you established the view.

To specify a disposition for the data you are currently viewing, supply a value for *disposition*. The value determines what data will be in the window after the CALL to CSRVIEW completes.

- For a permanent object that has no scroll area:
  - To retain the data that is currently in the window, supply a value of RETAIN for *disposition*.
  - To discard the data that is currently in the window, supply a value of REPLACE for *disposition*. After the operation completes, the window contents are unpredictable.

For example, assume that a window is mapped to one block of a permanent object that has no scroll area. The window contains the character string AAA.....A and the block to which the window is mapped contains BBB.....B. If you specify a value of RETAIN, upon completion of the CALL, the window still contains AAA.....A, and the mapped block contains BBB.....B. If you specify a value of REPLACE, upon completion of the CALL, the window contents are unpredictable and the mapped block still contains BBB.....B.

- For a permanent object that has a scroll area or for a temporary object:
  - To retain the data that is currently in the window, supply a value of RETAIN for *disposition*. CSRVIEW also updates the mapped blocks of the scroll area or temporary object so that they contain the same data as the window.
  - To discard the data that is currently in the window, supply a value of REPLACE for *disposition*. Upon completion of the operation, the window contents are unpredictable.

For example, assume that a window is mapped to one block of a temporary object. The window contains the character string AAA.....A and the block to which the window is mapped contains BBB.....B. If you specify a value of RETAIN, upon completion of the CALL, the window still contains AAA.....A and the mapped block of the object also contains AAA.....A. If you specify a value of REPLACE, upon completion of the CALL, the window contents are unpredictable and the mapped block still contains BBB.....B.

CSRVIEW ignores the values you assign to the other parameters.

When you terminate the view of an object, the type of object that is mapped and the value you specify for *disposition* determine whether CSRVIEW updates the mapped blocks. CSRVIEW updates the mapped blocks of a temporary object or a permanent object's scroll area if you specify a disposition of RETAIN. In all other cases, to update the mapped blocks, call the appropriate service before terminating the view:

- To update a temporary object, or to update the scroll area of a permanent object, call CSRSCOT.
- To update an object on DASD, call CSRSAVE.

Upon successful completion of the CSRVIEW operation, the content of the window depends on the value specified for disposition. The window is no longer mapped to a scroll area or to an object, however. The storage used for the window is available for other use, perhaps to use as a window for a different part of the same object or to use as a window for a different object.

---

## Terminating Access to a Data Object

When you finish using a data object, you must terminate access to the object. When you terminate access, window services returns to the system any virtual storage it obtained for the object: storage for a temporary object or storage for a scroll area. If the object is temporary, window services deletes the object. If the object is permanent and window services dynamically allocated the data set when you requested access to the object, window services dynamically unallocates the data set. Your window is no longer mapped to the object or to a scroll area.

When you terminate access to a permanent object, window services does not update the object on DASD with changes that are in a window or the scroll area. To update the object, call CSRSAVE before terminating access to the object.

To terminate access to an object, call CSRIDAC and supply a value of END for *operation\_type*. To identify the object, supply an object identifier for *object\_id*. The value you supply for *object\_id* must be the same value CSRIDAC returned when you obtained access to the object.

Upon successful completion of the call, the storage used for the window is available for other use, perhaps as a window for viewing a different part of the same object or to use as a window for viewing a different object.

---

## Handling Return Codes and Abnormal Terminations

Each time you call a service, your program receives either a return code and reason code or an abend code and a reason code. These codes indicate whether the service completed successfully, encountered an unusual condition, or was unable to complete successfully.

When you receive a return code that indicates a problem or an unusual condition, your program can either attempt to correct the problem or can terminate its execution. Return codes and reason codes are explained in Chapter 3. Window Services with the description of each callable service program.

When an abend occurs, the system passes control to a recovery routine, if you or your installation have provided one. A recovery routine might be able to correct the problem that caused the abend and allow your program to continue execution. If a recovery routine has been provided, it can handle the abend condition the same way it handles other abend conditions. If a recovery routine has not been provided, the system terminates execution of your program. For an explanation of the abend codes, see *OS/390 MVS System Codes*.

---

## Chapter 3. Window Services

To use window services, you issue CALLs that invoke the appropriate window services program. Each service program performs one or more functions and requires a set of parameters coded in a specific order on the CALL statement.

Depending on the function requested from a service, there might be one or more parameter values that the service ignores. Although a service might ignore a parameter value, you must still code that parameter on the CALL statement. Because the service ignores the parameter value, you can assign the parameter any value that is acceptable for the parameter's data type. If the service uses a particular parameter value, the CALL statement description in this chapter defines the allowable values that you can assign to the parameter.

This chapter describes the CALL statements that invoke window services. Each description includes a syntax diagram, parameter descriptions, and return code and reason code explanations with recommended actions. Return codes and reason codes are shown in hexadecimal followed by the decimal equivalent enclosed in parentheses. For examples of how to code the CALL statements, see "Chapter 4. Window Services Coding Examples" on page 4-1.

This chapter contains the following topics:

- "CSREVV — View an Object and Sequentially Access It"
- "CSRIDAC — Request or Terminate Access to a Data Object" on page 3-5
- "CSRREFR — Refresh an Object" on page 3-10
- "CSRSAVE — Save Changes Made to a Permanent Object" on page 3-12
- "CSRSCOT — Save Object Changes in a Scroll Area" on page 3-15
- "CSRVIEW — View an Object" on page 3-17

---

### CSREVV — View an Object and Sequentially Access It

Call CSREVV if you reference data in a sequential pattern and you want to:

- Map a window to one or more blocks (4096 bytes) of a data object. If you specified scrolling when you called CSRIDAC to identify the object, CSREVV maps the window to the blocks in the scroll area and maps the scroll area to the object.
- Specify how many blocks window services is to bring into the window each time CSREVV needs more data from the object.

Mapping a data object enables your program to access the data that is viewed through the window the same way it accesses other data in your storage.

The CSREVV and CSRVIEW services differ on how to specify sequential access:

- If you use CSRVIEW and specify **sequential**, when you reference data that is not in your window, window services reads up to 16 blocks — the one that contains the data your program requests, plus the next 15 consecutive blocks. The number of consecutive blocks varies, depending on the size of the window and the availability of central storage.
- If you use CSREVV, you can specify the number of additional consecutive blocks that window services reads into the window at one time. The number ranges from 0 through 255.

## CSREVV

Use CSREVV if your program has sequential access and can benefit from having more than 16 blocks come into a window at one time, or fewer than 16 blocks at one time.

Code the CALL following the syntax of the high-level language you are using and specifying all parameters in the order shown below. For parameters that CSREVV uses to obtain input values, assign appropriate values. For parameters that CSREVV ignores, assign any value that is valid for the particular parameter's data type.

- To map a window to a data object and begin viewing the object, specify BEGIN and SEQ and assign values, acceptable to CSREVV, to:
  - *object\_id*
  - *offset*
  - *span*
  - *window\_name*
  - *disposition*
  - *pfcount*

CSREVV returns values in *return\_code* and in *reason\_code*.

- To end the view and unmap the data object, use CSRVIEW END and specify all values, except for *pfcount*, that you specified when you mapped the window.

CALL CSREVV	(operation_type ,object_id ,offset ,span ,window_name ,usage ,disposition ,pfcount ,return_code ,reason_code)
-------------	--

### **operation\_type**

Specify BEGIN to request that CSREVV map a data object.

### **,object\_id**

Specifies the object identifier. Supply the object identifier that CSRIDAC returned when you obtained access to the object.

Define *object\_id* as character data of length 8.

### **,offset**

Specifies the offset of the view into the object. Specify the offset in blocks of 4096 bytes.

Define *offset* as integer data of length 4.

### **,span**

Specifies the window size in blocks of 4096 bytes.

Define *span* as integer data of length 4.

**,window\_name**

Specifies the symbolic name you assigned to the window in your address space.

**,usage**

Specify SEQ to tell CSREVV that the expected pattern of references to data in the object will be sequential.

Define this field as character data of length 6. Pad the string on the right with 1 blank.

**,disposition**

Defines how CSREVV is to handle data that is in the window when you begin a view. When you specify CSREVV BEGIN and a disposition of:

**REPLACE** The first time you reference a block to which the window is mapped, CSREVV replaces the data in the window with the data from the referenced block.

**RETAIN** When you reference a block to which the window is mapped, the data in the window remains unchanged. When you call CSRSAVE to save the mapped blocks, CSRSAVE saves all of the mapped blocks because CSRSAVE considers them changed.

Define *disposition* as character data of length 7. If you specify RETAIN, pad the string on the right with 1 blank.

**,pfcount**

Specifies the number of additional blocks you want window services to bring into the window each time your program references data that is not already in the window. The number you specify is added to the minimum of one block that window services always brings in. That is, if you specify a value of 20, window services brings in a total of 21. The number of additional blocks ranges from zero through 255.

Define *pfcount* as integer data of length 4.

**,return\_code**

When CSREVV completes, *return\_code* contains the return code. Define *return\_code* as integer data of length 4.

Return codes and reason codes are explained under “Return Codes and Reason Codes” on page 3-4.

**,reason\_code**

When CSREVV completes, *reason\_code* contains the reason code. Define *reason\_code* as integer data of length 4.

Return codes and reason codes are explained under “Return Codes and Reason Codes” on page 3-4.

## Abend Codes

CSREVV issues abend code X'019'. For more information, see *OS/390 MVS System Codes*.

## Return Codes and Reason Codes

When CSREVV returns control to your program, *return\_code* contains a return code and *reason\_code* contains a reason code. Return codes and reason codes are shown in hexadecimal followed by the decimal equivalent enclosed in parentheses. Table 3-1 identifies return code and reason code combinations, tells what each means, and recommends an action that you should take.

A return code of X'4' with a reason code of X'0125' or a return code of X'C' with any reason code means that data-in-virtual encountered a problem or an unexpected condition. Data-in-virtual reason codes, which are two bytes long and right justified, are explained in *OS/390 MVS Programming: Assembler Services Reference*. To resolve a data-in-virtual problem, request help from your system programmer.

Table 3-1. CSREVV Return and Reason Codes

Return Code	Reason Code	Meaning and Action
00000000 (0)	00000000 (0)	<b>Meaning:</b> The operation was successful. <b>Action:</b> Continue normal program execution.
00000004 (4)	xxxx0125 (293)	<b>Meaning:</b> The operation was successful. The service could not retain all the data that was in the scroll area, however. <b>Action:</b> Notify your system programmer.
00000012 (18)	xxxx000A (10)	<b>Meaning:</b> There is another service currently executing with the specified ID. <b>Action:</b> Use a different ID or wait until the other service completes. If the problem persists, notify your system programmer.
0000000C (12)	xxxx0017 (23)	<b>Meaning:</b> An I/O error has occurred. <b>Action:</b> Notify your system programmer.
0000000C (12)	xxxx001A (26)	<b>Meaning:</b> The specified range does not encompass any mapped area of the object. <b>Action:</b> If you expect this reason code, take whatever action the design of your program dictates. If the reason code is unexpected, check your program for errors: you might have specified the wrong range of blocks on CSRVIEW or on CSRREFR. If you do not find any errors in your program, notify your system programmer.
0000000C (12)	xxxx001C (28)	<b>Meaning:</b> The object cannot be accessed at the current time. <b>Action:</b> Try running your program at a later time. If the problem persists, notify your system programmer.
0000000C (12)	xxxx0040 (64)	<b>Meaning:</b> The specified MAP range would cause the hiperspace data-in-virtual object to be extended such that the installation data space limits would be exceeded. <b>Action:</b> Change the MAP range you have specified or request your system programmer to increase the installation's data space limits.
0000000C (12)	xxxx0801 (2049)	<b>Meaning:</b> System error — Insufficient storage available to build the necessary data-in-virtual control block structure. <b>Action:</b> Notify your system programmer.

Table 3-1. CSREVV Return and Reason Codes (continued)

Return Code	Reason Code	Meaning and Action
0000000C (12)	xxxx0802 (2050)	<b>Meaning:</b> System error — I/O driver failure. <b>Action:</b> Notify your system programmer.
0000000C (12)	xxxx0803 (2051)	<b>Meaning:</b> System error — A necessary page table could not be read into real storage. <b>Action:</b> Notify your system programmer.
0000000C (12)	xxx00804 (2052)	<b>Meaning:</b> System error — Catalog update failed. <b>Action:</b> Notify your system programmer.
0000000C (12)	xxxx0806 (2054)	<b>Meaning:</b> System error — I/O error. <b>Action:</b> Notify your system programmer.
0000000C (12)	xxxx0808 (2056)	<b>Meaning:</b> System error — I/O from a previous request has not completed. <b>Action:</b> Notify your system programmer.
0000002C (44)	00000004 (4)	<b>Meaning:</b> Window services have not been defined to your system or the link to the service failed. <b>Action:</b> Notify your system programmer.

---

## CSRIDAC — Request or Terminate Access to a Data Object

Call CSRIDAC to:

- Request access to a data object
- Terminate access to a data object

Code the CALL following the syntax of the high-level language you are using and specifying all parameters in the order shown below. For parameters that CSRIDAC uses to obtain input values, assign values that are acceptable to CSRIDAC. For parameters that CSRIDAC ignores, assign any value that is valid for the particular parameter's data type.

The parameter values that CSRIDAC uses depends on whether you are requesting access to an object or terminating access.

- To request access to a data object, specify BEGIN for *operation\_type*, and assign values, acceptable to CSRIDAC, to the following parameters:
  - *object\_type*
  - *object\_name* if the object is permanent
  - *scroll\_area*
  - *object\_state* if the object is permanent and *object\_type* specifies DSNAME
  - *access\_mode* if the object exists and is permanent
  - *object\_size* if the object is new or temporary
  - *object\_size* if the object is new or temporary

CSRIDAC ignores other parameter values. CSRIDAC returns values in *object\_id*, *high\_offset*, *return\_code*, and *reason\_code*.

- To terminate access to a data object, specify END for *operation\_type*, and assign a value, acceptable to CSRIDAC, to *object\_id*. CSRIDAC ignores other parameter values. CSRIDAC returns values in *return\_code* and *reason\_code*.

## CSRIDAC

CALL CSRIDAC	(operation_type ,object_type ,object_name ,scroll_area ,object_state ,access_mode ,object_size ,object_id ,high_offset ,return_code ,reason_code)
--------------	---

### **operation\_type**

Specifies the type of operation the service is to perform:

- To request access to an object, specify BEGIN.
- To terminate access to an object, specify END. If the object is temporary, CSRIDAC deletes it.

Define *operation\_type* as character data of length 5. If you specify END, pad the string on the right with 1 or 2 blanks.

### **,object\_type**

Specifies the type of object. The types are:

- DDNAME** The object is an existing (OLD) VSAM linear data set allocated to the file whose DDNAME is specified by *object\_name*.
- DSNAME** The object is the linear VSAM data set whose name is specified by *object\_name*. The data set may already exist or may be a new data set that you want window services to create.
- TEMPSPACE** The object is a temporary data object. Window services deletes the object when your program calls CSRIDAC and *operation\_type* equals END.

If *operation\_type* is BEGIN, you must supply a value.

Define this parameter as character data of length 9. If you specify either DDNAME or DSNAME, pad the string on the right with 1 to 3 blanks.

### **,object\_name**

Specifies the data set name of a permanent object or the DDNAME of a data definition (DD) statement that defines a permanent object.

- If *object\_type* is DDNAME, *object\_name* must contain the name of a DD statement.
- If *object\_type* is DSNAME, *object\_name* must contain the data set name of the permanent object.

If *operation\_type* is BEGIN and *object\_type* is DDNAME or DSNAME, you must supply a value for *object\_name*.

Define *object\_name* as character data of length 1 to 45. If *object\_name* contains fewer than 45 characters, pad the name on the right with a blank.

### **,scroll\_area**

Specifies whether window services is to create a scroll area for the data object.

**YES** Create a scroll area.

**NO** Do not create a scroll area.

If *operation\_type* is BEGIN and *object\_type* is TEMPSPACE, specify YES.

Define *scroll\_area* as character data of length 3. If you specify NO, pad the string on the right with a blank.

**,object\_state**

Specifies the state of the object.

**OLD** The object exists.

**NEW** The object does not exist and window services must create it.

If *operation\_type* is BEGIN and *object\_type* is DSNAME, you must supply a value for *object\_state*.

Define *object\_state* as character data of length 3.

**,access\_mode**

Specifies the type of access required.

**READ** READ access.

**UPDATE** UPDATE access.

If *operation\_type* is BEGIN and *object\_type* is DDNAME or DSNAME, you must supply a value for *access\_mode*. For a new or temporary data object, window services assumes UPDATE.

Define *access\_mode* as character data of length 6. If you specify READ, pad the string on the right with 1 or 2 blanks.

**,object\_size**

Specifies the maximum size of the new object in units of 4096 bytes.

This parameter is required if either of the following conditions is true:

- *Operation\_type* is BEGIN, *object\_type* is DSNAME, and *object\_state* is NEW
- *Operation\_type* is BEGIN and *object\_type* is TEMPSPACE

Define *object\_size* as integer data of length 4.

**,object\_id**

Specifies the object identifier.

When *operation\_type* is BEGIN, the service returns the object identifier in this parameter. Use the identifier to identify the object to other window services.

When *operation\_type* is END, you must supply the object identifier in this parameter.

Define *object\_id* as character data of length 8.

**,high\_offset**

When CSRIDAC completes, *high\_offset* contains the size of the existing object expressed in blocks of 4096 bytes

Define *high\_offset* as integer data of length 4.

**,return\_code**

When CSRIDAC completes, *return\_code* contains the return code. Define *return\_code* as integer data of length 4.

## CSRIDAC

Return codes and reason codes are explained under “Return Codes and Reason Codes”.

### ,reason\_code

When CSRIDAC completes, *reason\_code* contains the reason code. Define *reason\_code* as integer data of length 4.

Return codes and reason codes are explained under “Return Codes and Reason Codes”.

## Abend Codes

CSRIDAC issues abend code X'019'. For more information, see *OS/390 MVS System Codes*.

## Return Codes and Reason Codes

When CSRIDAC returns control to your program, *return\_code* contains a return code and *reason\_code* contains a reason code. Return codes and reason codes are shown in hexadecimal followed by the decimal equivalent enclosed in parentheses. Table 3-2 identifies return code and reason code combinations, tells what each means, and recommends an action that you should take.

A return code of X'C' means that data-in-virtual encountered a problem or an unexpected condition. The associated reason codes are data-in-virtual reason codes. Data-in-virtual reason codes are two bytes long and right justified. To resolve a data-in-virtual problem, request help from your system programmer. For information about data-in-virtual, see the *OS/390 MVS Programming: Assembler Services Guide*.

Table 3-2. CSRIDAC Return and Reason Codes

Return Code	Reason Code	Meaning and Action
00000000 (0)	00000000 (0)	<b>Meaning:</b> The operation was successful. <b>Action:</b> Continue normal program execution.
00000008 (8)	00000118 (280)	<b>Meaning:</b> The system could not obtain enough storage to create a hiperspace for the temporary object or the scroll area. <b>Note:</b> Hiperspace is the name the system uses to identify the storage it uses to create a temporary object or a scroll area for a permanent object. <b>Action:</b> Notify your system programmer. The system programmer might have to increase the SMF limit for data spaces and hiperspace that are intended for the user.
00000008 (8)	00000119 (281)	<b>Meaning:</b> The system could not delete or unidentify the temporary object or the scroll area. <b>Action:</b> Notify your system programmer.
00000008 (8)	0000011A (282)	<b>Meaning:</b> The system was unable to create a new VSAM linear data set. DFP 3.1 must be running and SMS must be active. <b>Action:</b> Notify your system programmer.

Table 3-2. CSRIDAC Return and Reason Codes (continued)

Return Code	Reason Code	Meaning and Action
0000000C (12)	xxxx000A (10)	<b>Meaning:</b> Another service currently is executing with the specified ID.  <b>Action:</b> Use a different ID or wait until the other service completes. If the problem persists, notify your system programmer.
0000000C (12)	xxxx001C (28)	<b>Meaning:</b> The object cannot be accessed at the current time.  <b>Action:</b> Try running your program at a later time. If the problem persists, notify your system programmer.
0000000C (12)	xxxx0037 (55)	<b>Meaning:</b> The caller invoked ACCESS. The access is successful, but the system is issuing a warning that the data set was not allocated with a SHAREOPTIONS(1,3).  <b>Action:</b> Notify your system programmer.
0000000C (12)	xxxx003E (62)	<b>Meaning:</b> The hiperspace data-in-virtual object may not be accessed at this time. (If MODE=READ, the object is already accessed under a different ID for UPDATE. If MODE=UPDATE, the object is already accessed under at least one other ID.)  <b>Action:</b> Try running your program at a later time. If the problem persists, notify your system programmer.
0000000C (12)	xxxx0801 (2049)	<b>Meaning:</b> System error — Insufficient storage available to build the necessary data-in-virtual control block structure.  <b>Action:</b> Notify your system programmer.
0000000C (12)	xxxx0802 (2050)	<b>Meaning:</b> System error — I/O driver failure.  <b>Action:</b> Notify your system programmer.
0000000C (12)	xxxx0805 (2053)	<b>Meaning:</b> System error — A system error of indeterminate origin has occurred.  <b>Action:</b> Notify your system programmer.
0000000C (12)	xxxx0808 (2056)	<b>Meaning:</b> System error — I/O from a previous request has not completed.  <b>Action:</b> Notify your system programmer.
00000010 (16)	rrrrnnnn	<b>Meaning:</b> The system was unable to allocate or unallocate the data set specified as <i>object_name</i> . The value <i>rrrr</i> is the return code from dynamic allocation. The value <i>nnnn</i> is the two-byte reason code from dynamic allocation. See <i>OS/390 MVS Programming: Authorized Assembler Services Guide</i> for dynamic allocation return and reason codes.  <b>Action:</b> If <i>object_state</i> is NEW, make sure that a data set of the same name does not already exist. If one does already exist, either use the existing data set or change the name of your data set. If you are unable to correct the problem, notify your system programmer.
0000002C (44)	00000004 (4)	<b>Meaning:</b> Window services have not been defined to your system or the link to the service failed.  <b>Action:</b> Notify your system programmer.

## CSRREFR — Refresh an Object

To refresh changed data that is in a window, a scroll area, or a temporary object, call CSRREFR. CSRREFR refreshes changed data within specified blocks as follows:

- If the object is permanent, CSRREFR replaces specified changed blocks in windows or the scroll area with corresponding blocks from the object on DASD.
- For a temporary object, CSRREFR refreshes specified changed blocks in windows and the object by setting the blocks to binary zeroes.

Code the CALL following the syntax of the high-level language you are using and specifying all parameters in the order shown below. For parameters that CSRREFR uses to obtain input values, assign values that are acceptable to CSRREFR. For parameters that CSRREFR ignores, assign any value that is valid for the particular parameter's data type.

Assign values, acceptable to CSRREFR, to *object\_id*, *offset*, and *span*. CSRREFR ignores other parameter values. CSRREFR returns values in *return\_code* and *reason\_code*.

CALL CSRREFR	(object_id ,offset ,span ,return_code ,reason_code)
--------------	---

### **object\_id**

Specifies the object identifier. Supply the same object identifier that CSRIDAC returned when you obtained access to the object.

Define *object\_id* as character data of length 8.

### **,offset**

Specifies the offset into the object in blocks of 4096 bytes. A value of 0 specifies the first block of 4096 bytes or bytes 0 to 4095 of the object; a value of 1 specifies the second block of 4096 bytes, or bytes 4096 to 8191 of the object, and so forth.

Define *offset* as integer data of length 4.

*offset* and *span*, together, determine which part of the object window services refreshes. To refresh the entire object, specify 0 for *offset* and 0 for *span*.

### **,span**

Specifies how many 4096-byte blocks CSRREFR is to refresh.

Define *span* as integer data of length 4.

### **,return\_code**

When CSRREFR completes, *return\_code* contains the return code. Define *return\_code* as integer data of length 4.

Return codes and reason codes are explained under "Return Codes and Reason Codes" on page 3-11.

**,reason\_code**

When CSRREFR completes, *reason\_code* contains the reason code. Define *reason\_code* as integer data of length 4.

Return codes and reason codes are explained under “Return Codes and Reason Codes”.

## Abend Codes

CSRREFR issues abend code X'019'. For more information, see *OS/390 MVS System Codes*.

## Return Codes and Reason Codes

When CSRREFR returns control to your program, *return\_code* contains a return code and *reason\_code* contains a reason code. Return codes and reason codes are shown in hexadecimal followed by the decimal equivalent enclosed in parentheses. Table 3-3 identifies return code and reason code combinations, tells what each means, and recommends an action that you should take.

A return code of X'C' means that data-in-virtual encountered a problem or an unexpected condition. The associated reason codes are data-in-virtual reason codes. Data-in-virtual reason codes are two bytes long and right justified. To resolve a data-in-virtual problem, request help from your system programmer.

Table 3-3. CSRREFR Return and Reason Codes

Return Code	Reason Code	Meaning and Action
00000000 (0)	00000000 (0)	<b>Meaning:</b> The operation was successful. <b>Action:</b> Continue normal program execution.
00000008 (8)	00000152 (338)	<b>Meaning:</b> The system could not refresh all of the temporary object within the specified span. <b>Action:</b> Notify your system programmer.
0000000C (12)	xxxx000A (10)	<b>Meaning:</b> There is another service currently executing with the specified ID. <b>Action:</b> Use a different ID or wait until the other service completes. If the problem persists, notify your system programmer.
0000000C (12)	xxxx0017 (23)	<b>Meaning:</b> An I/O error has occurred. <b>Action:</b> Notify your system programmer.
0000000C (12)	xxxx001A (26)	<b>Meaning:</b> The specified range does not include any mapped block of the object. <b>Action:</b> If you expect this reason code, take whatever action the design of your program dictates. If the reason code is unexpected, check your program for errors: you might have specified the wrong range of blocks on CSRVIEW or on CSRREFR. If you do not find any errors in your program, notify your system programmer.
0000000C (12)	xxxx0801 (2049)	<b>Meaning:</b> System error — Insufficient storage available to build the necessary data-in-virtual control block structure. <b>Action:</b> Notify your system programmer.

## CSRREFR

Table 3-3. CSRREFR Return and Reason Codes (continued)

Return Code	Reason Code	Meaning and Action
0000000C (12)	xxxx0803 (2051)	<b>Meaning:</b> System error — A necessary page table could not be read into real storage.  <b>Action:</b> Notify your system programmer.
0000000C (12)	xxxx0805 (2053)	<b>Meaning:</b> System error — A system error of indeterminate origin has occurred.  <b>Action:</b> Notify your system programmer.
0000000C (12)	xxxx0806 (2054)	<b>Meaning:</b> System error — I/O error.  <b>Action:</b> Notify your system programmer.
0000000C (12)	xxxx0808 (2056)	<b>Meaning:</b> System error — I/O from a previous request has not completed.  <b>Action:</b> Notify your system programmer.
0000002C (44)	00000004 (4)	<b>Meaning:</b> Window services have not been defined to your system or the link to the service failed.  <b>Action:</b> Notify your system programmer.

---

## CSRSAVE — Save Changes Made to a Permanent Object

To update specified blocks of a permanent object with changes, call CSRSAVE. The changes can be in blocks that are mapped to the scroll area, in blocks that are mapped to windows, or in a combination of these places.

### Usage Note

You cannot use CSRSAVE to save changes made to a temporary object. If you call CSRSAVE for a temporary object, CSRSAVE ignores the request and returns control to your program with a return code of 8. To save changes made to a temporary object, call CSRSCOT.

Code the CALL following the syntax of the high-level language you are using and specifying all parameters in the order shown below. For parameters that CSRSAVE uses to obtain input values, assign values that are acceptable to CSRSAVE. For parameters that CSRSAVE ignores, assign any value that is valid for the particular parameter's data type.

Assign values, acceptable to CSRSAVE, to *object\_id*, *offset*, and *span*. CSRSAVE ignores other parameter values. CSRSAVE returns values in *new\_hi\_offset*, *return\_code*, and *reason\_code*.

CALL CSRSAVE	(object_id ,offset ,span ,new_hi_offset ,return_code ,reason_code)
--------------	---

**object\_id**

Specifies the object identifier. Supply the same object identifier that CSRIDAC returned when you obtained access to the object.

Define *object\_id* as character data of length 8.

**,offset**

Specifies the offset into the object in blocks of 4096 bytes. A value of 0 specifies the first block of 4096 bytes or bytes 0 to 4095 of the object; a value of 1 specifies the second block of 4096 bytes, or bytes 4096 to 8191 of the object, and so forth.

Define *offset* as integer data of length 4.

*offset* and *span*, together, determine which part of the object window services saves. To save the entire object, specify 0 for *offset* and 0 for *span*.

**,span**

Specifies how many 4096-byte blocks CSRSAVE is to save.

Define *span* as integer data of length 4.

**,new\_hi\_offset**

When CSRSAVE completes, *new\_hi\_offset* contains the new size of the object expressed in units of 4096 bytes.

Define *new\_hi\_offset* as integer data of length 4.

**,return\_code**

When CSRSAVE completes, *return\_code* contains the return code. Define *return\_code* as integer data of length 4.

Return codes and reason codes are explained under "Return Codes and Reason Codes".

**,reason\_code**

When CSRSAVE completes, *reason\_code* contains the reason code. Define *reason\_code* as integer data of length 4.

Return codes and reason codes are explained under "Return Codes and Reason Codes".

## Abend Codes

CSRSAVE issues abend code X'019'. For more information, see *OS/390 MVS System Codes*.

## Return Codes and Reason Codes

When CSRSAVE returns control to your program, *return\_code* contains a return code and *reason\_code* contains a reason code. Return codes and reason codes are shown in hexadecimal followed by the decimal equivalent enclosed in parentheses. Table 3-4 on page 3-14 identifies return code and reason code combinations, tells what each means, and recommends an action that you should take.

A return code of X'4' with a reason code of X'0807' or a return code of X'C' with any reason code means that data-in-virtual encountered a problem or an unexpected condition. Data-in-virtual reason codes are two bytes long and right justified. To

## CSRSAVE

resolve a data-in-virtual problem, request help from your system programmer. For information about data-in-virtual, see the *OS/390 MVS Programming: Assembler Services Guide*.

Table 3-4. CSRSAVE Return and Reason Codes

Return Code	Reason Code	Meaning and Action
00000000 (0)	00000000 (0)	<b>Meaning:</b> The operation was successful. <b>Action:</b> Continue normal program execution.
00000004 (4)	xxxx0807 (2055)	<b>Meaning:</b> Media damage may be present in allocated DASD space. The damage is beyond the currently saved portion of the object. The SAVE operation completed successfully. <b>Action:</b> Notify your system programmer.
00000008 (8)	xxxx0143 (323)	<b>Meaning:</b> You cannot use the SAVE service for a temporary object. <b>Action:</b> Use the scrollout (CSRSCOT) service.
0000000C (12)	xxxx000A (10)	<b>Meaning:</b> There is another service currently executing with the specified ID. <b>Action:</b> Use a different ID or wait until the other service completes. If the problem persists, notify your system programmer.
0000000C (12)	xxxx0017 (23)	<b>Meaning:</b> An I/O error has occurred. <b>Action:</b> Notify your system programmer.
0000000C (12)	xxxx001A (26)	<b>Meaning:</b> The specified range does not encompass any mapped area of the object. <b>Action:</b> If you expect this reason code, take whatever action the design of your program dictates. If the reason code is unexpected, check your program for errors: you might have specified the wrong range of blocks on CSRVIEW or on CSRREFR. If you do not find any errors in your program, notify your system programmer.
0000000C (12)	xxxx0801 (2049)	<b>Meaning:</b> System error — Insufficient storage available to build the necessary data-in-virtual control block structure. <b>Action:</b> Notify your system programmer.
0000000C (12)	xxxx0802 (2050)	<b>Meaning:</b> System error — I/O driver failure. <b>Action:</b> Notify your system programmer.
0000000C (12)	xxxx0803 (2051)	<b>Meaning:</b> System error — A necessary page table could not be read into real storage. <b>Action:</b> Notify your system programmer.
0000000C (12)	xxxx0804 (2052)	<b>Meaning:</b> System error — Catalog update failed. <b>Action:</b> Notify your system programmer.
0000000C (12)	xxxx0806 (2054)	<b>Meaning:</b> System error — I/O error. <b>Action:</b> Notify your system programmer.

Table 3-4. CSRSAVE Return and Reason Codes (continued)

Return Code	Reason Code	Meaning and Action
0000000C (12)	xxxx0808 (2056)	<b>Meaning:</b> System error — I/O from a previous request has not completed.  <b>Action:</b> Notify your system programmer.
0000002C (44)	00000004 (4)	<b>Meaning:</b> Window services have not been defined to your system or the link to the service failed.  <b>Action:</b> Notify your system programmer.

## CSRSCOT — Save Object Changes in a Scroll Area

Call CSRSCOT to:

- Update specified blocks of a permanent object’s scroll area with changes that appear in a window you have defined for the object. CSRSCOT requires that the permanent object have a scroll area. CSRSCOT changes only the content of the scroll area and not the content of the permanent data object.
- Update specified blocks of a temporary data object with the changes that appear in a window you have defined for the data object.

Code the CALL following the syntax of the high-level language you are using and specifying all parameters in the order shown below. For parameters that CSRSCOT uses to obtain input values, assign values that are acceptable to CSRSCOT. For parameters that CSRSCOT ignores, assign any value that is valid for the particular parameter’s data type.

Assign values, acceptable to CSRSCOT, to *object\_id*, *offset*, and *span*. CSRSCOT ignores other parameter values. CSRSCOT returns values in *return\_code* and *reason\_code*.

CALL CSRSCOT	( <i>object_id</i> , <i>offset</i> , <i>span</i> , <i>return_code</i> , <i>reason_code</i> )
--------------	--

### **object\_id**

Specifies the object identifier. Supply the same object identifier that CSRIDAC returned when you obtained access to the object.

Define *object\_id* as character data of length 8.

### **,offset**

Specifies the offset into the object in blocks of 4096 bytes. A value of 0 specifies the first block of 4096 bytes or bytes 0 to 4095 of the object; a value of 1 specifies the second block of 4096 bytes, or bytes 4096 to 8191 of the object, and so forth.

Define *offset* as integer data of length 4.

*offset* and *span*, together, determine which part of the object CSRSCOT updates. To update the entire object, specify 0 for *offset* and 0 for *span*.

## CSRSCOT

### ,span

Specifies how many 4096-byte blocks CSRSCOT is to update.

Define *span* as integer data of length 4.

### ,return\_code

When CSRSCOT completes, *return\_code* contains the return code. Define *return\_code* as integer data of length 4.

Return codes and reason codes are explained under "Return Codes and Reason Codes".

### ,reason\_code

When CSRSCOT completes, *reason\_code* contains the reason code. Define *reason\_code* as integer data of length 4.

Return codes and reason codes are explained under "Return Codes and Reason Codes".

## Abend Codes

CSRSCOT issues abend code X'019'. For more information, see *OS/390 MVS System Codes*.

## Return Codes and Reason Codes

When CSRSCOT returns control to your program, *return\_code* contains a return code and *reason\_code* contains a reason code. Return codes and reason codes are shown in hexadecimal followed by the decimal equivalent enclosed in parentheses. Table 3-5 identifies return code and reason code combinations, tells what each means, and recommends an action that you should take.

A return code of X'C' means that data-in-virtual encountered a problem or an unexpected condition. The associated reason codes are data-in-virtual reason codes. Data-in-virtual reason codes are two bytes long and right justified. For information about data-in-virtual, see *OS/390 MVS Programming: Assembler Services Guide*. To resolve the problem, request help from your system programmer.

Table 3-5. CSRSCOT Return and Reason Codes

Return Code	Reason Code	Meaning and Action
00000000 (0)	00000000 (0)	<b>Meaning:</b> The operation was successful. <b>Action:</b> Continue normal program execution.
00000004 (4)	xxxx0807 (2055)	<b>Meaning:</b> Media damage may be present in allocated DASD space. The damage is beyond the currently saved portion of the object. The SAVE operation completed successfully. <b>Action:</b> Notify your system programmer.
0000000C (12)	xxxx000A (10)	<b>Meaning:</b> There is another service currently executing with the specified ID. <b>Action:</b> Use a different ID or wait until the other service completes. If the problem persists, notify your system programmer.

Table 3-5. CSRSCOT Return and Reason Codes (continued)

Return Code	Reason Code	Meaning and Action
0000000C (12)	xxxx0017 (23)	<b>Meaning:</b> An I/O error has occurred. <b>Action:</b> Notify your system programmer.
0000000C (12)	xxxx001A (26)	<b>Meaning:</b> The specified range does not encompass any mapped area of the object. <b>Action:</b> If you expect this reason code, take whatever action the design of your program dictates. If the reason code is unexpected, check your program for errors: you might have specified the wrong range of blocks on CSRVIEW or on CSRREFR. If you do not find any errors in your program, notify your system programmer.
0000000C (12)	xxxx0801 (2049)	<b>Meaning:</b> System error — Insufficient storage available to build the necessary data-in-virtual control block structure. <b>Action:</b> Notify your system programmer.
0000000C (12)	xxxx0802 (2050)	<b>Meaning:</b> System error — I/O driver failure. <b>Action:</b> Notify your system programmer.
0000000C (12)	xxxx0803 (2051)	<b>Meaning:</b> System error — A necessary page table could not be read into real storage. <b>Action:</b> Notify your system programmer.
0000000C (12)	xxxx0804 (2052)	<b>Meaning:</b> System error — Catalog update failed. <b>Action:</b> Notify your system programmer.
0000000C (12)	xxxx0806 (2054)	<b>Meaning:</b> System error — I/O error. <b>Action:</b> Notify your system programmer.
0000000C (12)	xxxx0808 (2056)	<b>Meaning:</b> System error — I/O from a previous request has not completed. <b>Action:</b> Notify your system programmer.
0000002C (44)	00000004 (4)	<b>Meaning:</b> Window services have not been defined to your system or the link to the service failed. <b>Action:</b> Notify your system programmer.

---

## CSRVIEW — View an Object

Call CSRVIEW to:

- Map a window to one or more blocks of a data object. If you specified scrolling when you called CSRIDAC to identify the object, CSRVIEW maps the window to the scroll area and the scroll area to the object.
- Specify that the reference pattern you are using is either random or sequential.
- End a view that you previously created through CSRVIEW or CSREVIEW and unmap the object.

Mapping a data object enables your program to access the data that is viewed through the window the same way it accesses other data in your storage.

## CSRVIEW

The CSREVV service also maps a data object. Use that service if your program can benefit from having more than 16 blocks come into a window at one time or if it can benefit from having fewer than 16.

Code the CALL following the syntax of the high-level language you are using and specifying all parameters in the order shown below. For parameters that CSRVIEW uses to obtain input values, assign values that are acceptable to CSRVIEW. For parameters that CSRVIEW ignores, assign any value that is valid for the particular parameter's data type.

The type of function you request determines which parameter values CSRVIEW uses to obtain input values:

- To map a window to a data object and begin viewing the object, specify BEGIN for *operation\_type*, and assign values, acceptable to CSRVIEW, to:
  - *object\_id*
  - *offset*
  - *span*
  - *window\_name*
  - *usage*
  - *disposition*

CSRVIEW ignores other parameter values. CSRVIEW returns values in *return\_code* and in *reason\_code*.

- To end a view set by either CSRVIEW or CSREVV and to unmap the data object, specify END for *operation\_type*, and assign values, acceptable to CSRVIEW, to:
  - *object\_id*
  - *offset*
  - *span*
  - *window\_name*
  - *usage*
  - *disposition*

CSRVIEW ignores other parameter values. CSRVIEW returns values in *return\_code* and *reason\_code*.

CALL CSRVIEW	(operation_type ,object_id ,offset ,span ,window_name ,usage ,disposition ,return_code ,reason_code)
--------------	--

### **operation\_type**

Specifies the type of operation CSRVIEW is to perform. To begin viewing an object, specify BEGIN. To end a view, specify END.

Define *operation\_type* as character data of length 5. If you specify END, pad the string on the right with 1 or 2 blanks.

**,object\_id**

Specifies the object identifier. Supply the object identifier that CSRIDAC returned when you obtained access to the object.

Define *object\_id* as character data of length 8.

**,offset**

Specifies the offset of the view into the object. Specify the offset in blocks of 4096 bytes.

Define *offset* as integer data of length 4.

**,span**

Specifies the window size in blocks of 4096 bytes.

Define *span* as integer data of length 4.

**,window\_name**

Specifies the symbolic name you assigned to the window in your address space.

**,usage**

Specifies the expected pattern of references to pages in the object. Specify one of the following values:

- SEQ**            The reference pattern is expected to be sequential. If you specify SEQ, window services brings up to 16 blocks of data into the window at a time, depending on the size of the window.
- RANDOM**        The reference pattern is expected to be random. If you specify RANDOM, window services brings data into the window one block at a time.

Define *usage* as character data of length 6. If you specify SEQ, pad the string on the right with 1 to 3 blanks.

**,disposition**

Defines how CSRVIEW is to handle data that is in the window when you begin or end a view.

- When you specify CSRVIEW with an *operation\_type* of BEGIN and a disposition of:

**REPLACE**        The first time you reference a block to which the window is mapped, CSRVIEW replaces the data in the window with the data from the referenced block.

**RETAIN**          When you reference a block to which the window is mapped, the data in the window remains unchanged. When you call CSRSAVE to save the mapped blocks, CSRSAVE saves all of the mapped blocks because CSRSAVE considers them changed.

- When you specify CSRVIEW with an *operation\_type* of END and a disposition of:

**REPLACE**        CSRVIEW discards the data that is in the window making the window contents unpredictable. CSRVIEW does not update mapped blocks of the object or scroll area.

## CSRVIEW

**RETAIN** If the object is permanent and has no scroll area, CSRVIEW retains the data that is in the window. CSRVIEW does not update mapped blocks of the object. If the object is permanent and has a scroll area, or if the object is temporary, CSRVIEW retains the data that is in the window and updates the mapped blocks of the object or scroll area.

Define *disposition* as character data of length 7. If you specify RETAIN, pad the string on the right with a blank.

### **,return\_code**

When CSRVIEW completes, *return\_code* contains the return code. Define *return\_code* as integer data of length 4.

Return codes and reason codes are explained under "Return Codes and Reason Codes".

### **,reason\_code**

When CSRVIEW completes, *reason\_code* contains the reason code. Define *reason\_code* as integer data of length 4.

Return codes and reason codes are explained under "Return Codes and Reason Codes".

## Abend Codes

CSRVIEW issues abend code X'019'. For more information, see *OS/390 MVS System Codes*.

## Return Codes and Reason Codes

When CSRVIEW returns control to your program, *return\_code* contains a return code and *reason\_code* contains a reason code. Return codes and reason codes are shown in hexadecimal followed by the decimal equivalent enclosed in parentheses. Table 3-6 identifies return code and reason code combinations, tells what each means, and recommends an action that you should take.

A return code of X'4' with a reason code of X'0125' or a return code of X'C' with any reason code means that data-in-virtual encountered a problem or an unexpected condition. Data-in-virtual reason codes are two bytes long and right justified. For information about data-in-virtual, see *OS/390 MVS Programming: Assembler Services Guide*. To resolve the problem, request help from your system programmer.

Table 3-6. CSRVIEW Return and Reason Codes

Return Code	Reason Code	Meaning and Action
00000000 (0)	00000000 (0)	<b>Meaning:</b> The operation was successful. <b>Action:</b> Continue normal program execution.
00000004 (4)	xxxx0125 (293)	<b>Meaning:</b> The operation was successful. The service could not retain all the data that was in the scroll area, however. <b>Action:</b> Notify your system programmer.

Table 3-6. CSRVIEW Return and Reason Codes (continued)

Return Code	Reason Code	Meaning and Action
0000000C (12)	xxxx000A (10)	<b>Meaning:</b> There is another service currently executing with the specified ID.  <b>Action:</b> Use a different ID or wait until the other service completes. If the problem persists, notify your system programmer.
0000000C (12)	xxxx0017 (23)	<b>Meaning:</b> An I/O error has occurred.  <b>Action:</b> Notify your system programmer.
0000000C (12)	xxxx001A (26)	<b>Meaning:</b> The specified range does not encompass any mapped area of the object.  <b>Action:</b> If you expect this reason code, take whatever action the design of your program dictates. If the reason code is unexpected, check your program for errors: you might have specified the wrong range of blocks on CSRVIEW or on CSRREFR. If you do not find any errors in your program, notify your system programmer.
0000000C (12)	xxxx001C (28)	<b>Meaning:</b> The object cannot be accessed at the current time.  <b>Action:</b> Try running your program at a later time. If the problem persists, notify your system programmer.
0000000C (12)	xxxx0040 (64)	<b>Meaning:</b> The specified MAP range would cause the hiperspace data-in-virtual object to be extended such that the installation data space limits would be exceeded.  <b>Action:</b> Change the MAP range you have specified or request your system programmer to increase the installation's data space limits.
0000000C (12)	xxxx0801 (2049)	<b>Meaning:</b> System error — Insufficient storage available to build the necessary data-in-virtual control block structure.  <b>Action:</b> Notify your system programmer.
0000000C (12)	xxxx0802 (2050)	<b>Meaning:</b> System error — I/O driver failure.  <b>Action:</b> Notify your system programmer.
0000000C (12)	xxxx0803 (2051)	<b>Meaning:</b> System error — A necessary page table could not be read into real storage.  <b>Action:</b> Notify your system programmer.
0000000C (12)	xxx00804 (2052)	<b>Meaning:</b> System error — Catalog update failed.  <b>Action:</b> Notify your system programmer.
0000000C (12)	xxxx0806 (2054)	<b>Meaning:</b> System error — I/O error.  <b>Action:</b> Notify your system programmer.
0000000C (12)	xxxx0808 (2056)	<b>Meaning:</b> System error — I/O from a previous request has not completed.  <b>Action:</b> Notify your system programmer.
0000002C (44)	00000004 (4)	<b>Meaning:</b> Window services have not been defined to your system or the link to the service failed.  <b>Action:</b> Notify your system programmer.

## CSRVIEW

---

## Chapter 4. Window Services Coding Examples

The following examples show how to invoke window services from each of the supported languages. Following each program example is an example of the JCL needed to compile, link edit, and execute the program example. Use these examples to supplement and reinforce information that is presented elsewhere in this book.

**Note:** Included in the FORTRAN example is the code for a required assembler language program. This program ensures that the window for the FORTRAN program is aligned on a 4K boundary.

The examples are presented on the following pages:

- “ADA Example”
- “C/370 Example” on page 4-6
- “COBOL Example” on page 4-9
- “FORTRAN Example” on page 4-13
- “Pascal Example” on page 4-17
- “PL/I Example” on page 4-21

---

### ADA Example

```
-----
-- This program illustrates how Data Window services are invoked --
-- using ADA. Note that the data object referenced in this program --
-- is permanent and already allocated, and is defined by the DD --
-- statement CSRDD1 in the JCL.                                     --
--                                                                 --
-- This program must be linkedited with the CSR linkage-assist --
-- routines (also known as stubs) in SYS1.CSSLIB.                --

  -- When you want to map a window to your object, data window services
  -- expects the address of the start of the window to be on a page (4K)
  -- boundary, and the length of the window to be a multiple of 4096 bytes.
  -- If your window is an array, the address of the first element
  -- of the array must be on a page boundary. If this is not the case,
  -- you can appropriately choose one slice of your array that starts
  -- on a 4K boundary and is a multiple of 4096 bytes in length to map
  -- onto your object.
  -- To illustrate, consider the array A(1..max_len). If the address of
  -- A(1) is not on page boundary, you cannot map A(1..max_len) to your
  -- object. You can, however, map A(n..m) to your object if you choose
  -- some appropriate values n and m such that A(n) starts on a 4K
  -- boundary and A(n..m) is a multiple of 4096 bytes in length.

  Ad := Integer_Address(Sp(1)'Address); -- Get address of start of array

  -- Determine the first element whose address is on page boundary
  -- and use that element as the origin of the array.

  -- You can pass an array slice as a parameter to a non-Ada subprogram,
  -- and because the slice is a composite object, the parameter list

```

## ADA Example

```
-- contains the actual address of the first element in the slice.
-- To elaborate further:
-- Scalar data is passed by copy, but composite data is passed by
-- reference. If the scalar value was passed as a scalar, the assemble\
-- program would receive the address of the copy and not the address of
-- the scalar. By passing the scalar value as an array slice, a
-- composite data type is being passed and thus is passed by reference.
-- Using this technique, the assembler code receives the actual address
-- of the scalar, not a copy of the scalar.

## Chapter 5. Introduction to Reference Pattern Services

Reference pattern services allow HLL programs to define a reference pattern for a specified area of virtual storage that the program is about to reference. Additionally, the program specifies how much data it wants the operating system to bring into central storage at one time. Data and instructions in virtual storage must reside in central storage before they can be processed. The system honors the request according to the availability of central storage. By bringing in more data at one time, the system might improve the performance of your program.

The term **reference pattern** refers to the order in which a program's instructions process a range of data, such as an array or part of an array.

Programs that benefit most from reference pattern services are those that reference amounts of data that are greater than one megabyte. The program should reference the data in a sequential manner and in a consistent direction, either forward or backward. In forward direction, the program references data elements in order of ascending addresses. In backward direction, the program references data elements in order of decreasing addresses. In addition, if the program "skips over" certain areas, and these areas are of uniform size and are repeated at regular intervals throughout the area, reference pattern services might provide additional performance improvement.

Two reference pattern services are available through program CALLs:

- CSRIRP identifies the range of data and the reference pattern, and defines the number of bytes that the system is requested to bring into central storage at one time. These activities are called "defining the reference pattern".
- CSRRRP removes the definition; it tells the system that the program has stopped using the reference pattern with the range of data.

A program might have a number of different ways of referencing a particular area. In this case, the program can issue multiple pairs of CSRIRP and CSRRRP services for the area. Only one pattern can be in effect at a time.

Although reference pattern services can be used for data structures other than arrays, for simplicity, examples in this chapter and in the next use the services with arrays.

---

### How Does the System Manage Data?

Before you can evaluate the performance advantage that reference pattern services offer, you must understand some facts about how the operating system handles the data your program references. The system divides the data into 4096-byte chunks; each chunk is called a "page". For the processor to execute an instruction, the page that contains the data that the instruction requires must reside in central storage. Central storage contains pages of data for many programs — your program, plus other programs that the system is working on. The system brings a page of your data into central storage when your program needs data on that page. If the program uses the data in a sequential manner, once the program finishes using the data on that page, it will not immediately use the page again. After your program finishes using that page, the system might remove the page from central storage to make room for another page of your data or maybe a page of some other

program's data. The system allows pages to stay in central storage if they are referenced frequently enough and if the system does not need those pages for other programs.

The process that the system goes through when it pauses to bring a page into central storage is called a "page fault". This interruption causes the system to stop working on your program (or "suspend" your program) while more of your program's data comes into central storage. Then, when the page is in central storage and the system is available to your program again, the system resumes running your program at the instruction where it left off.

Reference pattern services can change the way the system handles your program's data. With direction from reference pattern services, the system moves multiple pages into central storage at a time. By bringing in many pages at a time, the system takes fewer page faults. Fewer page faults mean possible performance gains for your program.

---

## An Example of How the System Manages Data in an Array

To evaluate the performance advantage reference pattern services offers, you need to understand how the system handles a range of data. The best way to describe this is through an example of a simple two-dimensional array. As array A(i,j) of 3 rows and 4 columns illustrates, the system stores arrays in FORTRAN programs in column-major order and stores arrays in COBOL, Pascal, PL/1, and C programs in row-major order.

A(1,1)	A(1,2)	A(1,3)	A(1,4)
A(2,1)	A(2,2)	A(2,3)	A(2,4)
A(3,1)	A(3,2)	A(3,3)	A(3,4)

The system stores the elements of the arrays in the following order:

Sequence of Element in Storage	FORTRAN Array Element	COBOL, Pascal, PL/1, C Array Element
1	A(1,1)	A(1,1)
2	A(2,1)	A(1,2)
3	A(3,1)	A(1,3)
4	A(1,2)	A(1,4)
5	A(2,2)	A(2,1)
6	A(3,2)	A(2,2)
7	A(1,3)	A(2,3)
8	A(2,3)	A(2,4)
9	A(3,3)	A(3,1)
10	A(1,4)	A(3,2)
11	A(2,4)	A(3,3)
12	A(3,4)	A(3,4)

Examples in this chapter and the next depict data as a horizontal string. The elements in the arrays, therefore, would look like the following:

Location of elements

---

1   2   3   4   5   6   7   8   9   10   11   12

Consider a two-dimensional array, ARRAY1, that has 1024 columns and 1024 rows and each element is eight bytes in size. The size of the array, therefore, is 1048576 elements or 8388608 bytes. For simplicity, assume the array is aligned on a page boundary. Also, assume the data is not in central storage. The program references each element in the array in a forward direction, starting with the first element.

First, consider how the system brings data into central storage without information from reference pattern services. At the first reference of ARRAY1, the system takes a page fault and brings into central storage the page (of 4096 bytes) that contains the first element. After the program finishes processing the 512th (4096 divided by 8) element in the array, the system takes another page fault and brings in a second page. The system takes a page fault every 512 elements, throughout the array.

The following linear representation shows the elements in the array and the page faults the system takes as a program processes the array.

By bringing in one page at a time, the system takes 2048 page faults (8388608 divided by 4096), each page fault adding to the elapsed time of the program.

Suppose, through CSRIRP, the system knew in advance that a program would be using the array in a consistently forward direction. The system could then assume that the program's use of the pages of the array would be sequential. To decrease the number of page faults, each time the program requested data that was not in central storage, the system could bring in more than one page at a time. Suppose the system brought the next 20 consecutive pages (81920 bytes) of the array into central storage on each page fault. In this case, the system takes not 2048 page faults, but 103 (8388608 divided by 81920=102.4). Page faults occur in the array as follows:

The system brings in successive pages only to the end of the array.

Consider another way of referencing ARRAY1. The program references the first twenty elements, then skips over the next 1004 elements, and so forth through the array. CSRIRP allows you to tell the system to bring in only the pages that contain the data the program references. In this case, the reference pattern includes a repeating gap of 8032 bytes (1004×8) every 8192 bytes (1024×8). The pattern looks like this:

The grouping of consecutive bytes that the program references is called a **reference unit**. The grouping of consecutive bytes that the program skips over is

called a **gap**. Reference units and gaps alternate throughout the array at regular intervals. The reference pattern is as follows:

- The reference unit is 20 elements in size — 160 consecutive bytes that the program references.
- The gap is 1004 elements in size — 8032 consecutive bytes that the program skips over.

Figure 5-1 shows this reference pattern and the pages that the system does not bring into central storage.

## What Pages Does the System Bring in When a Gap Exists?

When a gap exists, the number of pages the system brings in depends on the size of the gap, the size of the reference unit, and where the page boundary lies in relation to the gap and the reference unit. The following examples illustrate those factors.

### Example 1

Figure 5-1 illustrates ARRAY1, the 1024-by-1024 array of eight-byte elements, where the program references 20 elements, then skips over the next 1004, and so forth in a forward direction throughout the array. The reference pattern includes a reference unit of 160 and a gap of 8032 bytes. The reference units begin on every other page boundary.

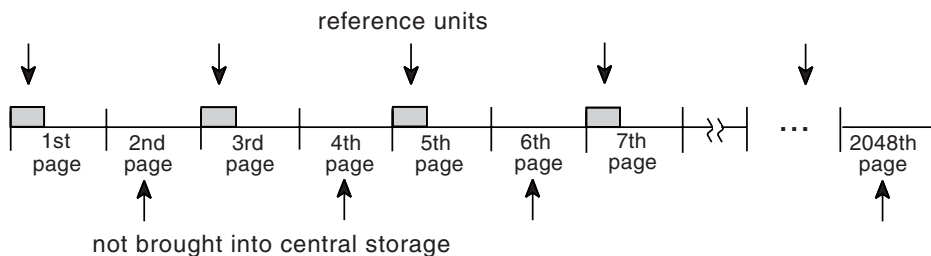

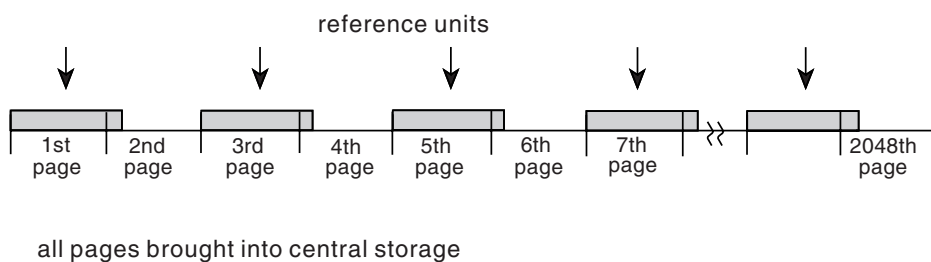

Figure 5-1. Illustration of a Reference Pattern with a Gap

Every other consecutive page of the data does not come into central storage; those pages contain only the “skipped over” data.

### Example 2

In example 2, the reference pattern includes a reference unit of 4800 bytes and a gap of 3392 bytes. The example assumes that the area to be referenced starts on a page boundary.

Because each page contains data that the program references, the system brings in all pages.

### Example 3

In example 3, the area to be referenced does not begin on a page boundary. The reference pattern includes a reference unit of 2000 bytes and a gap of 5000 bytes. When you specify a reference pattern that includes a gap, the reference unit must be at the start of the area, as the following illustration shows:

most pages brought into central storage

Because the gap is larger than 4096 bytes, some pages do not come into central storage. Notice that the system does not bring in the fifth page.

#### Summary of how the size of the gap affects the number of pages the system brings into central storage:

- If the gap is less than 4096 bytes, the system has to bring into central all pages of the array.
- If the gap is greater than 4095 bytes and less than 8192, the system might not have to bring in certain pages. Pages that contain only data in the gap do not come in.
- If the gap is greater than 8191 bytes, the system definitely does not have to bring in certain pages that contain the gap.

---

## Chapter 6. Using Reference Pattern Services

The two reference pattern services are CSRIRP and CSRRRP. First, you issue CALL CSRIRP to define a reference pattern for an area; then, issue CALL CSRRRP to remove the definition of reference pattern for the area. To avoid unnecessary processing, issue the calls outside of the loops that control processing of the data elements contained in the area.

---

### Defining the Reference Pattern for a Data Area

On CSRIRP, you tell the system:

- The lowest address of the area to be referenced
- The size of the area
- The direction of reference
- The reference pattern, in terms of reference unit and gap (if one exists)
- The number of reference units the system is to bring into central storage on a page fault

The system will not process CSRIRP unless the values you specify can result in a performance gain for your program. To make sure the system processes CSRIRP, ask the system to bring in more than three pages (that is, 12288 bytes) on each page fault.

Your program can have only one pattern defined for that area at one time. If your program will later reference the same area with another reference pattern, use CSRRRP to remove the definition, and then use CSRIRP to define another pattern.

Although the system brings in pages 4096 bytes at a time, you do not have to specify values on CSRIRP or CSRRRP in increments of 4096.

### Defining the Range of the Area

On CSRIRP, you define the range of the area to be referenced:

- *low\_address* identifies the lowest addressed byte in the range.
- *size* identifies the size, in bytes, of the range.

When reference is forward, *low\_address* identifies the first element that the program can reference in the range. When reference is backward, *low\_address* identifies the last element that the program can reference in the range: reference proceeds from the high-address end in the range towards *low\_address*.

The following parameters define the lowest address and the size of ARRAY1, a 1024-by-1024 array that consists of 8-byte elements. ARRAY1(1,1) identifies the element in the first row and the first column.

CSRIRP with low\_address of ARRAY1(1,1)  
size of 1024\*1024\*8 bytes

When a gap exists, define the range according to the following rules:

- If direction is forward, *low\_address* must be the first data element in a reference unit.
- If direction is backward, the value you use for *size* must be such that the first data element the program references is the high-address end of a reference unit.

These two rules are described and illustrated in “Using CSRIRP When a Gap Exists” on page 6-3.

## Identifying the Direction of the Reference

On *direction*, you specify the direction of reference through the array. Forward reference means instructions start with the element indicated by *low\_address* and proceed through the range of data specified by *size*. Backward reference means the program starts processing the high-address end of the range specified by *size* and proceeds toward the *low\_address* end.

- “+1” indicates forward direction.
- “-1” indicates backward direction.

An example of forward reference through ARRAY1 is specified as follows:

CSRIRP with direction of +1

“Using CSRIRP When a Gap Exists” on page 6-3 contains examples of forward and backward references when a gap exists.

## Defining the Reference Pattern

Figure 6-1 identifies two reference patterns that characterize most of the reference patterns that reference pattern services applies to.

Pattern #1: No uniform gap

Characteristics of pattern:

- No uniform gap
- Reference in regular intervals (such as every element) or in irregular intervals

Pattern #2: Uniform gap

Characteristics of pattern:

- Gaps of uniform size
- Reference units, uniform in size, that occur in a repeating pattern

Figure 6-1. Two Typical Reference Patterns

How you define the reference pattern depends on whether your program's reference pattern is like pattern #1 or pattern #2.

- **With pattern #1 where no uniform gap exists**, the program uses every element, every other element, or at least most elements on each page of array data. No definable gap exists. Do not use reference pattern services if the reference pattern is irregular and includes skipping over many areas larger than a page.
  - The *unitsize* parameter identifies the reference pattern; it indicates the number of bytes you want the system to use as a reference unit. Look at logical groupings of bytes, such as one row, a number of rows, or one element, if the elements are large in size. Or, you might choose to divide the area to be referenced, and bring in that area on a certain number of page faults. Use the value 0 on *gapsize*.

- The *units* parameter tells the system how many reference units to try to bring in on a page fault. For a reference pattern that begins on a page boundary and has no gaps, the total number of bytes the system tries to bring into central storage at a time is the value on *unitsize* times the number on *units*, rounded up to the nearest multiple of 4096. See “Choosing the Number of Bytes on a Page Fault” on page 6-4 for more information on how to choose the total number of bytes.
- **With pattern #2 where a uniform gap exists**, the pattern includes alternating gaps and reference units. Specify the reference pattern carefully. If you identify a reference pattern and do not adhere to it, the system will work harder than if you had not used the service.
  - The *unitsize* and *gapsize* parameters identify the reference pattern. Pattern #2 in Figure 6-1 on page 6-2 includes a reference unit of 20 bytes and a gap of 5000 bytes. Because the gap is greater than 4095, some pages of the array might not be brought into central storage.
  - The *units* parameter tells the system how many reference units to try to bring into central storage at a time. “What Pages Does the System Bring in When a Gap Exists?” on page 5-4 can help you understand how many bytes come into central storage at one time when a gap exists.

### Using CSRIRP When a Gap Exists

When a gap exists, you have to follow one of two rules in coding the two parameters, *low\_address* and *size*, that define the range of data. The direction of reference determines which rule you follow:

- **When reference is forward**, *low\_address* must identify the beginning of a reference unit.

Figure 6-2 illustrates forward reference through a range of data that includes gaps. Consider the reference pattern where the program references 2000 bytes and skips the next 5000 bytes, and so forth throughout the array. The range of data starts at *low\_address* and ends at the point identified in the figure by **A**. **A** can be any part of a gap or reference unit.

Figure 6-2. Illustration of Forward Direction of Reference

- **When reference is backward**, the value you code on *size* determines the location of the first element the program actually references. Calculate that value so that the first element the program references is the high-address end of a reference unit.

Figure 6-3 on page 6-4 illustrates backward reference through the same array as in Figure 6-2. Again, the program references 2000 bytes and skips the next 5000 bytes, and so forth throughout the array. The range starts at *low\_address* and ends at the point identified in the figure by **B**, where **B** must be the high-address end of a reference unit. *low\_address* can be any part of a gap or reference unit.

Figure 6-3. Illustration of Backward Direction of Reference

## Choosing the Number of Bytes on a Page Fault

An important consideration in using reference pattern services is how many bytes to ask the system to bring in on a page fault. To determine this, you need to understand some factors that affect the performance of your program.

Pages do not stay in central storage if they are not referenced frequently enough and other programs need that central storage. The longer it takes for a program to begin referencing a page in central storage, the greater the chance that the page has been moved out before being referenced. When you tell the system how many bytes it should try and bring into central at one time, you have to consider the following:

### 1. Contention for central storage

Your program contends for central storage along with all other submitted jobs. The greater the size of central storage, the more bytes you can ask the system to bring in on a page fault. The system responds with as much of the data you request as possible, given the availability of central storage.

### 2. Contention for processor time

Your program contends for the processor's attention along with all other submitted jobs. The more competition, the less the processor can do for your program and the smaller the number of bytes you should request.

### 3. The elapsed time of processing one page of your data

How long it takes a program to process a page depends on the number of references per page and the elapsed time per reference. If your program uses only a small percentage of elements on a page and references them only once or twice, the program completes the use of pages quickly. If the processing of each referenced element includes processor-intensive operations or a time-intensive operation, such as I/O, the time the program takes to process a page increases.

Conditions might vary between the peak activity of the daytime period and the low activity of the nighttime. You might be able to request a greater number at night than during the day.

*What if you specify too many bytes?* What if you ask the system to bring in so many pages that, by the time your program needs to use some of those pages, they have left central storage? The answer is that the system will have to bring them in again. This action causes an extra page fault and extra system overhead and decreases the benefit of reference pattern services.

For example, suppose you ask the system to bring in 204800 bytes, or 50 pages, at a time. But, by the time your program begins referencing the data on the 30th page, the system has moved that page and the ones after it out of central storage. It

moved them out because the program did not use them soon enough. In this case, your program has lost the benefit of moving the last 21 pages in. Your program would get more benefit by requesting fewer than 30 pages.

*What if you specify too few bytes?* If you specify too small a number, the system will take more page faults than it needs to and you are not taking full advantage of reference pattern services.

For example, suppose you ask the system to bring in 40960 bytes (or 10 pages) at a time. Your program's use of each page is not time-intensive, meaning that the program finishes using the pages quickly. The program can request a number greater than 10 without causing additional page faults.

**IBM recommends** that you use one of the following approaches, depending on whether you want to involve your system programmer in the decision.

- The first approach is the simple one. Choose a conservative number of bytes, around 81920 (20 pages), and run the program. Look for an improvement in the elapsed time. If you like the results, you might increase the number of bytes. If you continue to increase the number, at some point you will notice a diminishing improvement or even an increase in elapsed time. Do not ask for so much that your program or other programs suffer from degraded performance.
- The second approach is for the program that needs very significant performance improvements — those programs that require amounts in excess of 50 pages. If you have such a program, you and your system programmer should examine the program's elapsed time, paging speeds, and processor execution times. In fact, the system programmer can tune the system with your program in mind, providing the needed paging resources. *OS/390 MVS Initialization and Tuning Guide* can provide information on tuning the system.

Reference pattern services affects movement of pages from auxiliary **and** expanded storage to central storage. To gain insight into the effectiveness of your reference patterns, you and your system programmer will need the kind of information that the SMF Type 30 record provides. A Type 30 record includes counts of pages moved in anticipation of your program's use of those pages. The record provides counts of pages moved between expanded and central and between auxiliary and central. It also provides elapsed time values. Use this information to calculate rates of movement in determining whether to specify a very large number of bytes — for example, amounts greater than 204800 bytes (50 pages).

---

## Examples of Using CSRIRP to Define a Reference Pattern

To clarify the relationships between the *unitsize*, *gapsize*, and *units* parameters, this section contains three examples of defining a reference pattern. So that you can compare the three examples with what the system does without information from CSRIRP, the following call approximates the system's normal paging operation:

```
CSRIRP with unitsize of 4096 bytes  
           gapsize of 0 bytes  
           units of 1 reference unit (that is, one page)
```

Each time the system takes a page fault, it brings in 4096 bytes (one page), the system's reference unit. It brings in one reference unit at a time.

*Example 1* The program processes all elements in an array in a forward direction. The processing of each element is fairly simple. The program runs during the peak hours, and many programs compete for processor time and central storage. A

reasonable value to choose for the number of bytes to come into central on a page fault might be 80000 bytes (around 20 pages); *unitsize* can be 4000 bytes and *units* can be 20. The following CSRIRP service communicates this pattern to the system:

```
CSRIRP with unitsize of 4000 bytes
           gapsize of 0 bytes
           units of 20
           direction of +1
```

*Example 2* The program performs the same process as in Example 1, except the program does not reference every element in the array. The program runs during the night hours when contention for the processor and for central storage is light. In this case, a reasonable value to choose for the number of bytes to come into central storage on a page fault might be 200000 bytes (around 50 pages). *unitsize* can again be 4000 bytes and *units* can be 50. The following CSRIRP service communicates this pattern:

```
CSRIRP with unitsize of 4000 bytes
           gapsize of 0 bytes
           units of 50
           direction of +1
```

*Example 3* The program references in a consistently forward direction through the same large array. The pattern of reference in this example includes a gap. The program references 8192 bytes, then skips the next 4096 bytes, references the next 8192 bytes, skips the next 4096 bytes throughout the array. The program chooses to bring in data 8 pages at a time. Because of the placement of reference units and gaps on page boundaries, the system does not bring in the data in the gaps.

The following CSRIRP service reflects this reference pattern:

```
CSRIRP with unitsize of 4096*2 bytes
           gapsize of 4096 bytes
           units of 4
           direction of +1
```

where the system is to bring into central storage 8 pages (4x4096x2 bytes) on a page fault. The system's response to CSRIRP is illustrated as follows:

---

## Removing the Definition of the Reference Pattern

When a program is finished referencing the array in the way you specified on CSRIRP, use CSRRRP to remove the definition. The following example tells the system that the program in “Defining the Range of the Area” on page 6-1 has stopped referencing the array. *low\_address* and *size* have the same values you coded on the CSRIRP service that defined the reference pattern for that area.

```
CSRRRP with low_address of ARRAY1(1,1)
           size of 1024*1024*8 bytes
```

---

## Handling Return Codes

Each time you call CSRIRP or CSRRRP, your program receives a return code and a reason code. These codes indicate whether the service completed successfully or whether the system rejected the service.

When you receive a return code that indicates a problem or an unusual condition, try to correct the problem, and rerun the program. Return codes and reason codes are described in Chapter 7. Reference Pattern Services with the description of each reference pattern service.

---

## Chapter 7. Reference Pattern Services

To use reference pattern services, you issue CALLs that invoke the appropriate reference pattern services program. Each service program performs one or more functions and requires a set of parameters coded in a specific order on the CALL statement.

This chapter describes the CALL statements that invoke reference pattern services. Each description includes a syntax diagram, parameter descriptions, and return code and reason code explanations with recommended actions. For examples of how to code the CALL statements, see “Chapter 8. Reference Pattern Services Coding Examples” on page 8-1.

This chapter contains the following topics:

- “CSRIRP — Define a Reference Pattern”
- “CSRRRP — Remove a Reference Pattern” on page 7-3.

---

### CSRIRP — Define a Reference Pattern

Call CSRIRP to define a reference pattern for a large data area, such as an array, that you are about to reference. Through CSRIRP, you identify the data area and describe the reference pattern. Additionally, you tell the system how many bytes of data you want it to bring into central storage on a page fault (that is, each time the program references data that is not in central storage). This action might significantly improve the performance of the program.

Two parameters define the reference pattern:

- *unitsize* refers to a **reference unit** — a grouping of consecutive bytes that the program references.
- *gapsize* refers to a **gap** — a grouping of consecutive bytes that the program repeatedly skips over; when a pattern has a gap, reference units and gaps alternate throughout the data area.

Reference units and gaps must each be uniform in size and appear throughout the data area at repeating intervals.

Another parameter, *units*, allows you to specify how many reference units you want the system to bring into central storage each time the program references data that is not in central storage.

When you end the reference pattern in that data area, call the CSRRRP service.

Code the CALL following the syntax of the high-level language you are using and specifying all parameters in the order shown below. For parameters that CSRIRP uses to obtain input values, assign appropriate values.

On entry to CSRIRP, register 1 points to the reference pattern service parameter list. Note that when a FORTRAN program calls CSRIRP, and it is running in access register (AR) mode, register 1 does not point to the reference pattern service parameter list; it points to a list of parameter addresses. Each address in this list points to the data in the corresponding parameter of the reference pattern service parameter list. To use reference pattern services in this environment, the caller must provide an assembler interface routine to convert the FORTRAN parameter list to the form expected by reference services.

Assign values, acceptable to CSRIRP, to *low\_address*, *size*, *direction*, *unitsize*, *gapsize*, and *units*. CSRIRP returns values in *return\_code* and *reason\_code*.

CALL CSRIRP	(low_address ,size ,direction ,unitsize ,gapsize ,units ,return_code ,reason_code)
-------------	---

The parameters are explained as follows:

**low\_address**

Specifies the beginning point of the data to be referenced.

*low\_address* is the name of the data that resides at the beginning of the data area. When the direction is forward and a gap exists, *low\_address* must identify the beginning of a reference unit.

**,size**

Identifies the size, in bytes, of the data area to be accessed. When direction is backward and a gap exists, the value of *size* must be such that the first data element the program references is the high-address end of a reference unit.

Define *size* as integer data of length 4.

**,direction**

Indicates the direction of reference, either “+1” for forward or “-1” for backward.

Define *direction* as integer data of length 4.

**,unitsize**

Specifies the size of a reference unit.

If the pattern does not have a gap, define the reference unit as a logical grouping according to the structure of the data array. Examples are: one row, a number of rows, one element, or one page (4096 bytes). If the pattern has a gap, define *unitsize* as the grouping of bytes that the program references and *gap* as the grouping of bytes that the program skips over.

Define *unitsize* as integer data of length 4.

**,gapsize**

Specifies the size, in bytes, of a gap. If the pattern has a gap, define the gap as the grouping of bytes that the program skips over. If the pattern does not have a gap, use the value “0”.

Define *gapsize* as integer data of length 4.

**,units**

Indicates how many reference units the system is to bring into central storage each time the program needs data that is not in central storage.

Define *units* as integer data of length 4.

**,return\_code**

When CSRIRP completes, *return\_code* contains the return code. Define *return\_code* as integer data of length 4.

**,reason\_code**

When CSRIRP completes, *reason\_code* contains the reason code. Define *reason\_code* as integer data of length 4.

## Return Codes and Reason Codes

When CSRIRP returns control to your program, *return\_code* contains a return and *reason\_code* contains a reason code. The following table identifies return code and reason code combinations and tells what each means.

Return and reason codes, in hexadecimal, from CSRIRP are:

Return Code	Reason Code	Meaning
00	None	CSRIRP completed successfully.
04	xx0001xx	CSRIRP completed successfully; however, the system did not accept the reference pattern the caller specified. The system decided that bringing in pages of 4096 bytes would be more efficient.
08	xx0002xx	Unsuccessful completion. The range that the caller specified overlaps the range that a previous request specified.
08	xx0003xx	Unsuccessful completion. The number of CSRIRP requests for the user exceeds 100, the maximum number the system allows.
08	xx0004xx	Unsuccessful completion. Storage is not available for the CSRIRP service.
08	00000004	Unsuccessful completion. The direction that the caller specified is not valid.

---

## CSRRRP — Remove a Reference Pattern

Call CSRRRP to remove the reference pattern for a data area, as specified by the CSRIRP service. On CSRRRP, you identify the beginning of the data area and its size. Code *low\_address* and *size* exactly as you coded them on the CSRIRP service that defined the reference pattern.

Code the CALL following the syntax of the high-level language you are using and specifying all parameters in the order shown below. For parameters that CSRRRP uses to obtain input values, assign values that are acceptable to CSRRRP.

Assign values to CSRRRP, to *low\_address* and *size*. CSRRRP returns values in *return\_code* and *reason\_code*.

CALL CSRRRP	( <i>low_address</i> , <i>size</i> , <i>return_code</i> , <i>reason_code</i> )
-------------	---

The parameters are explained as follows:

## CSRRRP

### **low\_address**

Specifies the beginning point of the data to be referenced.

*low\_address* is the name of the data that resides at the beginning of the data area.

### **,size**

Specifies the size, in bytes, of the data area.

Define *size* as integer data of length 4.

### **,return\_code**

When CSRRRP completes, *return\_code* contains the return code. Define *return\_code* as integer data of length 4.

### **,reason\_code**

When CSRRRP completes, *reason\_code* contains the reason code. Define *reason\_code* as integer data of length 4.

## Return Codes and Reason Codes

When CSRRRP returns control to your program, *return\_code* contains a hexadecimal return code and *reason\_code* contains a hexadecimal reason code. The following table identifies return code and reason code combinations and tells what each means.

Return Code	Reason Code	Meaning
00	None	CSRRRP completed successfully.
08	xx0101xx	Unsuccessful completion. No CSRIRP service request was in effect for the specified data area. Check to see if the system rejected the previous CSRIRP request for the data area.

---

## Chapter 8. Reference Pattern Services Coding Examples

The following examples show how to invoke reference pattern services from each of the supported languages. Following each program example is an example of the JCL needed to compile, link edit, and execute the program example. Use these examples to supplement and reinforce information that is presented elsewhere in this book.

**Note:** Included in the FORTRAN example is the code for a required assembler language program. This program ensures that the reference pattern for the FORTRAN program is aligned on a 4K boundary.

The programs in this chapter are similar. They each process two arrays, A and B. The arrays are 200×200 in size, each element consisting of 4 bytes. Processing is as follows:

- Declare the arrays.
- Define reference patterns for A and B.
- Initialize A and B.
- Remove the definitions of the reference patterns for A and B.
- Define new reference patterns for A and B.
- Multiply A and B, generating array C.
- Remove the definitions of the reference patterns for A and B.

The examples are presented on the following pages:

- “C/370 Example”
- “COBOL Example” on page 8-4
- “FORTRAN Example” on page 8-8
- “Pascal Example” on page 8-11
- “PL/I Example” on page 8-13

---

### C/370 Example

The following example is coded in C/370:

```
#include <stdio.h>
#include <stdlib.h>
#include "csrbpc"

#define m 200
#define n 200
#define p 200
#define kelement_size 4
int chk_code(long int ret, long int reason, int linenumber);

main()
{
    long int A[m] [n];
    long int B[m] [n];
    long int C[m] [n];
    long int i;
    long int j;
    long int k;
    long int rc;
    long int rsn;
    long int arraysize;
    long int direction;
    long int unitsize;
    long int gap;
```

## C/370 Example

```
long int units;

arraysize = m*n*kelement_size;
direction = csr_forward;
unitsize = kelement_size*n;
gap = 0;
units = 20;

csrrip(A, &arraysize, &direction,;
      &unitsize,;
      &gap,;
      &units,;
      &rc,;
      &rsn);
chk_code(rc,rsn,__LINE__);

arraysize = m*p*kelement_size;

csrrip(B, &arraysize, &direction,;
      &unitsize,;
      &gap,;
      &units,;
      &rc,;
      &rsn);
chk_code(rc,rsn,__LINE__);
for (i=0; i<m; i++) {
  for (j=0; j<n; j++) {
    A[i][j] = i + j;
  }
}
for (i=0; i<n; i++) {
  for (j=0; j<p; j++) {
    B[i][j] = i + j;
  }
}

arraysize = m*n*kelement_size;

csrrrp(A, &arraysize,;
      &rc,;
      &rsn);
chk_code(rc,rsn,__LINE__);

arraysize = m*p*kelement_size;
csrrrp(B, &arraysize,;
      &rc,;
      &rsn);
chk_code(rc,rsn,__LINE__);

arraysize = m*n*kelement_size;
units = 25;
csrrip(A, &arraysize, &direction,;
      &unitsize,;
      &gap,;
      &units,;
      &rc,;
      &rsn);
chk_code(rc,rsn,__LINE__);

arraysize = n*p*kelement_size;
gap = (p-1)*kelement_size;
units = 50;
csrrip(B, &arraysize, &direction,;
      &unitsize,;
      &gap,;
      &units,;
```

```

        &rc,;
        &rsn);
chk_code(rc,rsn,__LINE__);
for (i=0; i<m; i++) {
    for (j=0; j<p; j++) {
        C[i][j] = 0;
        for (k=0; k<n; k++) {
            C[i][j] = C[i][j] + A[i][k] * B[k][j];
        }
    }
}
arraysize = m*n*kelement_size;
csrrrp(A, &arraysize,;
        &rc,;
        &rsn);
chk_code(rc,rsn,__LINE__);
arraysize = n*p*kelement_size;
csrrrp(B, &arraysize,;
        &rc,;
        &rsn);
chk_code(rc,rsn,__LINE__);
}

/* chk_code will check return code and reason code from previous */
/* calls to HLL services. It will print a message if any of the */

int chk_code(long int ret, long int reason, int linenum)
{
    if (ret != 0)
        printf("return_code = %ld instead of 0 at line %d\n",
               ret, linenum);
    if (reason != 0)

## Chapter 9. Using the Latch Manager Services

To use global resource serialization latch manager services, you issue CALLs from high level language programs. Each service requires a set of parameters coded in a specific order on the CALL statement.

This chapter describes the CALL statements that invoke latch manager services. Each description includes a syntax diagram, parameter descriptions, and return and reason code explanations with recommended actions. Return and reason codes are shown in hexadecimal and decimal, along with the associated equate symbol.

This chapter contains the following topics:

- “ISGLCRT — Create a Latch Set” on page 9-2
- “ISGLOBT — Obtain a Latch” on page 9-5
- “ISGLREL — Release a Latch” on page 9-8
- “ISGLPRG — Purge a Requestor from a Latch Set” on page 9-11
- “ISGLPBA — Purge a Group of Requestors from a Group of Latch Sets” on page 9-13

For information about the basic function of the latch manager, how to plan to use the latch manager, and how to use the latch manager callable services, see the serialization topic in *OS/390 MVS Programming: Authorized Assembler Services Guide*.

---

### Syntax and Linkage Conventions for Latch Manager Callable Services

The latch manager callable services have the following general calling syntax:

CALL *routine\_name(parameters)*

Some specific calling formats for languages that can invoke the latch manager callable services are:

**C** *routine\_name (parm1,parm2,...return\_code)*

**COBOL**

CALL “*routine\_name*” USING *parm1,parm2,...return\_code*

**FORTRAN**

CALL *routine\_name (parm1,parm2,...return\_code)*

**PL/I**

CALL *routine\_name (parm1,parm2,...return\_code)*

**REXX**

ADDRESS LU62 “*routine\_name parm1 parm2...return\_code*”

IBM provides files, called interface definition files (IDFs), that define variables and values for the parameters used with latch manager services. IBM provides IDFs for some of the listed languages. See the serialization topic in *OS/390 MVS Programming: Authorized Assembler Services Guide* for information about the IDFs that are available on MVS.

## ISGLCRT — Create a Latch Set

Call the Latch\_Create service to create a set of latches. Your application should call Latch\_Create during application initialization, and specify a number of latches that is sufficient to serialize all the resources that the application requires. Programs that run as part of the application can call the following related services:

- ISGLOBT** Requests exclusive or shared ownership of a latch.
- ISGLREL** Releases ownership of an owned latch or a pending request to obtain a latch.
- ISGLPRG** Purges all granted and pending requests for a particular requestor within a specific latch set.

In the following description of Latch\_Create, constants defined in the latch manager IDFs are followed by their numeric equivalents; you may specify either when coding calls to Latch\_Create.

Write the call as shown on the syntax diagram. You must code all parameters on the CALL statement in the order shown.

Assign values to the following parameters:

- number\_of\_latches
- latch\_set\_name
- create\_option

Latch\_Create returns values in the following parameters:

- latch\_set\_token
- return\_code

CALL ISGLCRT	(number_of_latches ,latch_set_name ,create_option ,latch_set_token ,return_code)
--------------	--

The parameters are explained as follows:

### **number\_of\_latches**

Specifies a fullword integer that indicates the number of latches to be created.

### **,latch\_set\_name**

Specifies a 48-byte area that contains the name of the latch set. The latch set name must be unique within the current address space. The latch set name can be any value up to 48 characters, but the first character must not be binary zeros or an EBCDIC blank. If the latch set name is less than 48 characters, it must be padded on the right with blanks.

IBM recommends that you use a standard naming convention for the latch set name. To avoid using a name that IBM uses, do not begin the latch set name with the character string **SYS**. It is a good idea to select a latch set name that is readable in output from the DISPLAY GRS command and interactive problem control system (IPCS). Avoid '@', '\$', and '#' because those characters do not always display consistently.

**,create\_option**

Specifies a fullword integer that must have a value of ISGLCRT\_PRIVATE (or a value of 0).

**,latch\_set\_token**

Specifies an 8-byte area to contain the latch set token returned by the Latch\_Create service. The latch set token uniquely identifies the latch set. Programs must specify this value on calls to the Latch\_Obtain, Latch\_Release, and Latch\_Purge services.

**,return\_code**

A fullword integer to contain the return code from the Latch\_Create service.

## ABEND Codes

The caller might encounter abend code X'9C6' for certain errors. See *OS/390 MVS System Codes* for explanations and responses.

## Return Codes

When the Latch\_Create service returns control to your program, return\_code contains a hexadecimal return code. The following table identifies return codes in hexadecimal and decimal (in parentheses), the equate symbol associated with each return code, the meaning of each return code, and a recommended action:

Table 9-1. ISGLCRT Return Codes

Return code and Equate symbol	Meaning and Action
00 (0) ISGLCRT_SUCCESS	<b>Meaning:</b> The Latch_Create service completed successfully. <b>Action:</b> None required.
04 (4) ISGLCRT_DUPLICATE_NAME	<b>Meaning:</b> The specified latch_set_name already exists, and is associated with a latch set that was created by a program running in the current primary address space. The latch manager does not create a new latch set. <b>Action:</b> To create a new latch set, specify a unique name on the latch_set_name parameter, then call the Latch_Create service again. Otherwise, continue processing with the returned latch set token.
10 (16) ISGLCRT_NO_STORAGE	<b>Meaning:</b> Environmental error. Not enough storage was available to contain the requested number of latches. The latch manager does not create a new latch set. <b>Action:</b> Specify a smaller value on the number_of_latches parameter.

## Examples of Calls to Latch Manager Services

The following is an example of how to call all the latch manager services in C language:

```

/*****/
/* C Example */
/*****/
#pragma linkage(setup, OS)
#pragma linkage(setprob, OS)
#include <ISGLMC.H> /* Include C language IDF */

main()

```

## ISGLCRT Callable Service

```

{
    const int numberOfLatches = 16; /* in this example we create 16
                                     latches */
    ISGLM_LSNM_type latchSetName
        = "EXAMPLE.ONE_LATCH_SET_NAME";
    ISGLM_LSTK_type latchSetToken; /* set up 48-byte latch set name */

```

---

## ISGLOBT — Obtain a Latch

Call the Latch\_Obtain service to request exclusive or shared ownership of a latch. When a requestor owns a particular latch, the requestor can use the resource associated with that latch. The following callable services are related to Latch\_Obtain:

- |                |   |
|----------------|---|
| <b>ISGLCRT</b> | Creates a latch set that an application can use to serialize resources.                         |
| <b>ISGLREL</b> | Releases ownership of an owned latch or a pending request to obtain a latch.                    |
| <b>ISGLPRG</b> | Purges all granted and pending requests for a particular requestor within a specific latch set. |

In the following description of Latch\_Obtain:

- The term *requestor* describes a task or SRB routine that calls the Latch\_Obtain service to request ownership of a latch.
- Constants defined in the latch manager IDFs are followed by their numeric equivalents; you may specify either when coding calls to Latch\_Obtain. For example, "ISGLOBT\_COND (value of 1)" indicates the constant ISGLOBT\_COND and its associated value, 1.

Write the call as shown on the syntax diagram. You must code all parameters on the CALL statement in the order shown.

Assign values to the following parameters:

- latch\_set\_token
- latch\_number
- requestor\_ID

## ISGLOBT Callable Service

- obtain\_option
- access\_option
- ECB\_address

Latch\_Obtain returns values in the following parameters:

- latch\_set\_token
- return\_code

Latch\_Obtain uses the following parameter for temporary storage:

- work\_area

CALL ISGLOBT	(latch_set_token ,latch_number ,requestor_ID ,obtain_option ,access_option ,ECB_address ,latch_token ,work_area ,return_code)
--------------	---

The parameters are explained as follows:

### **latch\_set\_token**

Specifies an 8-byte area that contains the latch\_set\_token that the Latch\_Create service returned earlier when it created the latch set.

### **,latch\_number**

Specifies a fullword integer that contains the number of the latch to be obtained. The latch\_number must be in the range from 0 to the total number of latches in the associated latch set minus one.

### **,requestor\_ID**

Specifies an 8-byte area that contains a value that identifies the caller of the Latch\_Obtain service. The requestor\_ID can be any value except all binary zeros.

Recovery routines can purge all granted and pending requests for a particular requestor (identified by a requestor\_id) within a specific latch set. When specifying the requestor\_ID on Latch\_Obtain, consider which latches would be purged if the Latch\_Purge service were to be called with the specified requestor\_ID. For more information about the Latch\_Purge service, see "ISGLPRG — Purge a Requestor from a Latch Set" on page 9-11.

### **,obtain\_option**

A fullword integer that specifies how the system is to handle the Latch\_Obtain request if the latch manager cannot immediately grant ownership of the latch to the requestor:

#### **ISGLOBT\_SYNC (value of 0)**

The system processes the request synchronously. The system suspends the requestor. When the latch manager eventually grants ownership of the latch to the requestor, the system returns control to the requestor.

#### **ISGLOBT\_COND (value of 1)**

The system processes the request conditionally. The system returns control

## ISGLOBT Callable Service

to the requestor with a return code of ISGLOBT\_CONTENTION (value of 4). The latch manager does not queue the request to obtain the latch.

### ISGLOBT\_ASYNC\_ECB (value of 2)

The system processes the request asynchronously. The system returns control to the requestor with a return code of ISGLOBT\_CONTENTION (value of 4). When the latch manager eventually grants ownership of the latch to the requestor, the system posts the ECB pointed to by the value specified on the ECB\_address parameter.

When you specify this option, the ECB\_address parameter must contain the address of an initialized ECB that is addressable from the home address space (HASN).

### ,access\_option

A fullword or character string that specifies the access required:

- ISGLOBT\_EXCLUSIVE (value of 0) - Exclusive (write) access
- ISGLOBT\_SHARED (value of 1) - Shared (read) access

### ,ECB\_address

Specifies a fullword that contains the address of an ECB. If you specify an obtain\_option of ISGLOBT\_SYNC (value of 0) or ISGLOBT\_COND (value of 1) on the call to Latch\_Obtain, the ECB\_address field must be valid (though its contents are ignored). IBM recommends that an address of 0 be used when no ECB is to be processed.

If you specify an obtain\_option of ISGLOBT\_ASYNC\_ECB (value of 2) and the system returns a return code of ISGLOBT\_CONTENTION (value of 4) to the caller, the system posts the ECB pointed to by the value specified on the ECB\_address parameter when the latch manager grants ownership of the latch to the requestor.

### ,latch\_token

Specifies an 8-byte area to contain the latch token returned by the Latch\_Obtain service. You must provide this value as a parameter on a call to the Latch\_Release service to release the latch.

### ,work\_area

Specifies a 256-byte work area that provides temporary storage for the Latch\_Obtain service. The work area should begin on a doubleword boundary to optimize performance. The work area must be in the same storage key as the caller of Latch\_Obtain.

### ,return\_code

Specifies a fullword integer that is to contain the return code from the Latch\_Obtain service.

## ABEND Codes

The caller might encounter abend code X'9C6' for certain errors. See *OS/390 MVS System Codes* for explanations and responses for these codes.

## Return Codes

When the Latch\_Obtain service returns control to your program, return\_code contains a hexadecimal return code. The following table identifies return codes in hexadecimal and decimal (in parentheses), the equate symbol associated with each return code, the meaning of each return code, and a recommended action:

## ISGLOBT Callable Service

Table 9-2. ISGLOBT Return Codes

Return code and Equate Symbol	Meaning and Action
00 (0) ISGLOBT_SUCCESS	<b>Meaning:</b> The Latch_Obtain service completed successfully. <b>Action:</b> None.
04 (4) ISGLOBT_CONTENTION	<b>Meaning:</b> A requestor called Latch_Obtain with an obtain_option of ISGLOBT_COND (value of 1) or ISGLOBT_ASYNC_ECB (value of 2). The latch is not immediately available. <b>Action:</b> If the requestor specified an obtain_option of ISGLOBT_COND (value of 1), no response is required. If the requestor specified an obtain_option of ISGLOBT_ASYNC_ECB (value of 2), and the latch is still required, wait on the ECB to be posted when the latch manager grants ownership of the latch to the requestor.

## Example

See “Examples of Calls to Latch Manager Services” on page 9-3 for an example of how to call Latch\_Obtain in C language.

---

## ISGLREL — Release a Latch

Call the Latch\_Release service to release ownership of an owned latch or a pending request to obtain a latch. Requestors should call Latch\_Release when the use of a resource associated with a latch is no longer required. The following callable services are related to Latch\_Release:

- ISGLCRT**      Creates a latch set that an application can use to serialize resources.
- ISGLOBT**      Requests exclusive or shared control of a latch.
- ISGLPRG**      Purges all granted and pending requests for a particular requestor within a specific latch set.

In the following description of Latch\_Release:

- The term *requestor* describes a program that calls the Latch\_Release service to release ownership of an owned latch or a pending request to obtain a latch.
- Constants defined in the latch manager IDFs are followed by their numeric equivalents; you may specify either when coding calls to Latch\_Obtain. For example, “ISGLREL\_COND (value of 1)” indicates the constant ISGLREL\_COND and its associated value, 1.

Write the CALL as shown on the syntax diagram, coding all parameters in the specified order.

Assign values to the following parameters:

- latch\_set\_token
- latch\_token
- release\_option

Latch\_Release returns a value in the following parameter:

- return\_code

Latch\_Release uses the following parameter for temporary storage:

- work\_area

CALL ISGLREL	(latch_set_token ,latch_token ,release_option ,work_area ,return_code)
--------------	--

The parameters are explained as follows:

#### **latch\_set\_token**

Specifies an 8-byte area that contains the latch set token returned to the caller of the Latch\_Create service. The latch set token identifies the latch set that contains the latch to be released.

#### **,latch\_token**

Specifies an 8-byte area that contains the latch token returned to the caller of the Latch\_Obtain service. The latch token identifies the request to be released.

#### **,release\_option**

Specifies a fullword integer that tells the latch manager what to do when the requestor either no longer owns the latch to be released or still has a pending request to obtain the latch to be released:

#### **ISGLREL\_UNCOND (value of 0)**

Abend the requestor:

- If a requestor originally specified an obtain\_option of ISGLOBT\_SYNC (value of 0) when obtaining the latch, the latch manager does not release the latch. The system abends the caller of Latch\_Release with abend X'9C6', reason code xxxx0009.
- If a requestor originally specified an obtain\_option of ISGLOBT\_ASYNC\_ECB (value of 2) when obtaining the latch, the latch manager does not release the latch. The system abends the caller of Latch\_Release with abend X'9C6', reason code xxxx0007.
- If the latch manager does not find a previous Latch\_Obtain request for the specified latch, the system abends the caller of Latch\_Release with abend X'9C6', reason code xxxx000A.

#### **ISGLREL\_COND (value of 1)**

Return control to the requestor:

- If a requestor originally specified an obtain\_option of ISGLOBT\_ASYNC\_ECB (value of 2) when obtaining the latch, the latch manager releases the request for ownership of the latch. The system returns control to the caller of Latch\_Release with a return code of ISGLREL\_NOT\_OWNED\_ECB\_REQUEST (value of 4).
- If a requestor originally specified an obtain\_option of ISGLOBT\_SYNC (value of 0) when obtaining the latch, the latch manager does not release the request for ownership of the latch. The system returns control to the caller of Latch\_Release with a return code of ISGLREL\_STILL\_SUSPENDED (value of 8).
- If the latch manager does not find a previous Latch\_Obtain request for the specified latch, the system returns control to the caller of

## ISGLREL Callable Service

Latch\_Release with a return code of  
ISGLREL\_INCORRECT\_LATCH\_TOKEN (value of 12).

### **,work\_area**

Specifies a 256-byte work area that provides temporary storage for the Latch\_Release service. The work area should begin on a doubleword boundary to optimize performance. The work area must be in the same storage key as the caller of Latch\_Release.

### **,return\_code**

Specifies a fullword integer that is to contain the return code from the Latch\_Release service.

## ABEND Codes

The caller might encounter abend code X'9C6' for certain errors. See *OS/390 MVS System Codes* for explanations and responses.

## Return Codes

When the Latch\_Release service returns control to your program, return\_code contains a hexadecimal return code. The following table identifies return codes in hexadecimal and decimal (in parentheses), the equate symbol associated with each return code, the meaning of each return code, and a recommended action:

Table 9-3. ISGLREL Return Codes

Return code and Equate Symbol	Meaning and Action
00 (0) ISGLREL_SUCCESS	<b>Meaning:</b> The Latch_Release service completed successfully. The caller released ownership of the specified latch request.  <b>Action:</b> None.
04 (4) ISGLREL_NOT_OWNED_ECB_REQUEST	<b>Meaning:</b> The requestor that originally called the Latch_Obtain service is still expecting the system to post an ECB (to indicate that the requestor has obtained the latch). The call to the Latch_Release service specified a release_option of ISGLREL_COND (value of 1). The latch manager does not post the ECB at the address specified on the original call to Latch_Obtain. The latch manager releases the latch.  <b>Action:</b> Validate the integrity of the resource associated with the latch (the requestor might have used the resource without waiting on the ECB). If the resource is undamaged, no action is necessary (a requestor routine may have been in the process of cancelling the request to obtain the latch).

Table 9-3. ISGLREL Return Codes (continued)

Return code and Equate Symbol	Meaning and Action
08 (8) ISGLREL_STILL_SUSPENDED	<p><b>Meaning:</b> Program error. The request specified a correct latch token, but the program that originally requested the latch is still suspended and waiting to obtain the latch.</p> <p>The latch requestor originally specified an <code>obtain_option</code> of <code>ISGLOBT_SYNC</code> on the call to the <code>Latch_Obtain</code> service. The call to the <code>Latch_Release</code> service specified a <code>release_option</code> of <code>ISGLREL_COND</code> (value of 1). The latch manager does not release the latch. The latch requestor remains suspended.</p> <p><b>Action:</b></p> <ul style="list-style-type: none"> <li>• Wait for the latch requestor to obtain the latch and receive control back from the system; then call the <code>Latch_Release</code> service again, or</li> <li>• End the program that originally requested the latch.</li> </ul>
0C (12) ISGLREL_INCORRECT_LATCH_TOKEN	<p><b>Meaning:</b> The latch manager could not find a granted or pending request associated with the value on the latch token parameter. The latch manager does not release a latch.</p> <p>This return code does not indicate an error if a routine calls <code>Latch_Release</code> to ensure that a latch is released. For example, if an error occurs when a requestor calls the <code>Latch_Obtain</code> service, the requestor's recovery routine might call <code>Latch_Release</code> to ensure that the requested latch is released. If the error prevented the requestor from obtaining the latch, the recovery routine receives this return code.</p> <p><b>Action:</b> If the return code is not expected, validate that the latch token is the same latch token returned to the caller of <code>Latch_Obtain</code>.</p>

## Example

See "Examples of Calls to Latch Manager Services" on page 9-3 for an example of how to call `Latch_Release` in C language.

---

## ISGLPRG — Purge a Requestor from a Latch Set

Call the `Latch_Purge` service to purge all granted and pending requests for a particular requestor within a specific latch set. Recovery routines should call `Latch_Purge` when one or more errors prevent requestors from releasing latches. The following callable services are related to `Latch_Purge`:

**ISGLCRT**      Creates a latch set that an application can use to serialize resources.

## ISGLPRG Callable Service

- ISGLOBT** Requests exclusive or shared control of a latch.
- ISGLREL** Releases control of an owned latch or a pending request to obtain a latch.

In the following description of Latch\_Purge, constants defined in the latch manager IDFs are followed by their numeric equivalents; you may specify either when coding calls to Latch\_Purge.

Write the CALL as shown on the syntax diagram. You must code all parameters on the CALL statement in the order shown.

Assign values to the following parameters:

- latch\_set\_token
- requestor\_ID

Latch\_Purge returns a value in the return\_code parameter.

CALL ISGLPRG	(latch_set_token ,requestor_ID ,return_code)
--------------	--

The parameters are explained as follows:

### **latch\_set\_token**

Specifies an 8-byte area that contains the latch\_set\_token previously returned by the Latch\_Create service. The latch set token identifies the latch set from which latch requests are to be purged.

### **,requestor\_ID**

Specifies an 8-byte area that contains the requestor\_ID originally specified on one or more previous calls to the Latch\_Obtain service. The Latch\_Purge service is to release all Latch\_Obtain requests that specify this requestor\_ID.

### **,return\_code**

A fullword integer that contains the return code from the Latch\_Purge service.

## ABEND Codes

The caller might encounter abend code X'9C6' for certain errors. See *OS/390 MVS System Codes* for explanations and responses.

## Return Codes

When the Latch\_Purge service returns control to your program, return\_code contains a hexadecimal return code. The following table identifies return codes in hexadecimal and decimal (in parentheses), the equate symbol associated with each return code, the meaning of each return code, and a recommended action:

Table 9-4. ISGLPRG Return Codes

Return code and Equate Symbol	Meaning and Action
00 (0) ISGLPRG_SUCCESS	<b>Meaning:</b> The Latch_Purge service completed successfully.  <b>Action:</b> None.

Table 9-4. ISGLPRG Return Codes (continued)

Return code and Equate Symbol	Meaning and Action
04 (4) ISGLPRG_DAMAGE_DETECTED	<p><b>Meaning:</b> Program error. While purging all requests for a particular requestor from a latch set, the latch manager found incorrect data in one or more latches. The latch manager tries to purge the latches that contain incorrect data, but the damage might prevent the latch manager from purging those latches. The latch manager purges the remaining latches (those with <i>correct</i> data) for the specified requestor.</p> <p><b>Action:</b> Take a dump and check for a storage overlay. If your application can continue without the resources serialized by the damaged latches, no action is required.</p>

## Example

See “Examples of Calls to Latch Manager Services” on page 9-3 for an example of how to call Latch\_Purge in C language.

---

## ISGLPBA — Purge a Group of Requestors from a Group of Latch Sets

Call the Latch\_Purge\_by\_Address\_Space service to purge all granted and pending requests for a group of requestors for a group of latch sets in the same address space. To effectively use this service, your latch\_set\_names and your requestor\_IDs should be defined such that they have a common portion and a unique portion. Groups of latch sets can then be formed by masking off the unique portion of the latch\_set\_name, and groups of latch requests in a latch set can then be formed by masking off the unique portion of the requestor\_ID. Masking off the unique portion of the requestor\_ID allows a single purge request to handle multiple latch sets and multiple requests in a latch set. Recovery routines should call Latch\_Purge\_by\_Address\_Space when one or more errors prevent requestors from releasing latches.

The following callable services are related to Latch\_Purge\_by\_Address\_Space:

<b>ISGLCRT</b>	Creates a latch set that an application can use to serialize resources.
<b>ISGLOBT</b>	Requests exclusive or shared control of a latch.
<b>ISGLREL</b>	Releases control of an owned latch or a pending request to obtain a latch.
<b>ISGLPRG</b>	Purges all granted and pending requests for a particular requestor within a specific latch set.

In the following description of Latch\_Purge\_by\_Address\_Space, equate symbols defined in the ISGLMASM macro are followed by their numeric equivalents; you may specify either when coding calls to Latch\_Purge\_by\_Address\_Space.

Write the CALL as shown on the syntax diagram. You must code all parameters on the CALL statement in the order shown.

Assign values to the following parameters:

- latch\_set\_token
- requestor\_ID

## ISGLPBA Callable Service

- requestor\_ID\_mask
- latch\_set\_name
- latch\_set\_name\_mask

Latch\_Purge\_by\_Address\_Space returns a value in the return\_code parameter.

CALL ISGLPBA	(latch_set_token ,requestor_ID ,requestor_ID_mask ,latch_set_name ,latch_set_name_mask ,return_code)
--------------	---

The parameters are explained as follows:

### **latch\_set\_token**

Specifies an 8-byte area that contains the latch\_set\_token previously returned by the Latch\_Create service or a value of zero. If the value is not zero, the latch\_set\_token identifies the latch set from which latch requests are to be purged. If the latch\_set\_token is set to zero, a group of latch sets, determined by the latch\_set\_name and latch\_set\_name\_mask, will have their latch requests purged.

### **,requestor\_id**

Specifies an 8-byte area that contains a portion of the requestor\_ID originally specified on one or more previous calls to the Latch\_Obtain service. This operand will be compared to the result of logically ANDing each requestor\_ID in the latch set with the requestor\_ID\_mask. Make sure that any corresponding bits that are zero in the requestor\_ID\_mask are also zero in this field, otherwise no ID matches will occur. Each requestor\_ID that has a name match will have its Latch\_Obtain requests released.

### **,requestor\_id\_mask**

Specifies an 8-byte area that contains the requestor\_ID\_mask that will be logically ANDed to each requestor\_ID in the latch set and then compared to the requestor\_ID operand. Each requestor\_ID that has a name match will have its Latch\_Obtain requests released.

### **,latch\_set\_name**

Specifies a 48-byte area that contains the portion of the latch\_set\_name that will be compared to the result of logically ANDing the latch\_set\_name\_mask with each latch set name in the primary address space. Make sure that any corresponding bits that are zero in the latch\_set\_name\_mask are also zero in this field, otherwise no name matches will occur. Each latch set that has a name match will have its Latch\_Obtain requests released. If the latch\_set\_token operand is non-zero this operand is ignored.

### **,latch\_set\_name\_mask**

Specifies a 48-byte area that contains the mask that will be logically ANDed to each of the latch set names in the primary address space and then compared to the latch\_set\_name operand. Each latch set that has a name match will have its Latch\_Obtain requests released. If the latch\_set\_token operand is non-zero this operand is ignored.

### **,return\_code**

A fullword integer that contains the return code from the Latch\_Purge\_By\_Address\_Space service.

## ABEND Codes

The caller might encounter abend code X'9C6' for certain errors. See *OS/390 MVS System Codes* for explanations and responses.

## Return Codes

When the Latch\_Purge\_by\_Address\_Space service returns control to your program, the return\_code contains a hexadecimal return code. The following table identifies return codes in hexadecimal and decimal (in parentheses), the equate symbol associated with each return code, the meaning of each return code, and a recommended action:

Table 9-5. ISGLPBA Return Codes

Return code and Equate Symbol	Meaning and Action
00 (0) ISGLPRG_SUCCESS	<p><b>Meaning:</b> The Latch_Purge_by_Address_Space service completed successfully.</p> <p><b>Action:</b> None.</p>
04 (4) ISGLPRG_DAMAGE_DETECTED	<p><b>Meaning:</b> Program error. While purging all requests for a particular requestor from a latch set, the latch manager found incorrect data in one or more latches. The latch manager tries to purge the latches that contain incorrect data, but the damage might prevent the latch manager from purging those latches. The latch manager purges the remaining latches (those with <i>correct</i> data) for the specified requestor.</p> <p><b>Action:</b> Take a dump and check for a storage overlay. If your application can continue without the resources serialized by the damaged latches, no action is required.</p>

## Chapter 10. Using Protected Resources

Many computer resources are so critical to a company's work that the integrity of these resources must be guaranteed. If changes to the data in the resources are corrupted by a hardware or software failure, human error, or a catastrophe, the computer must be able to restore the data. These critical resources are called *protected resources* or, sometimes, *recoverable resources*.

The system, when requested, can coordinate changes to one or more protected resources so that all changes are made or no changes are made. Resources that the system can protect are, for example:

- A hierarchical database
- A relational database
- A product-specific resource

*Resource recovery* is the protection of the resources. Resource recovery consists of the protocols and program interfaces that allow an application program to make consistent changes to multiple protected resources.

---

### Resource Recovery Programs

Three programs work together to protect resources:

- **Application program:** The application program accesses protected resources and requests changes to the resources.
- **Resource manager:** A resource manager is an authorized program that controls and manages access to a resource. A resource manager provides interfaces that allow the application program to read and change a protected resource. The resource manager also takes actions that commit or back out changes to a resource it manages.

Often an application changes more than one protected resource, so that more than one resource manager is involved.

A resource manager may be an IBM product, part of an IBM product, or a product from another vendor. A resource manager can be:

- A database manager, such as DB2
- A program, such as IMS/ESA Transaction Manager, that accepts work from an end user or another system and manages that work

**Note:** The resource manager in resource recovery is different from an RTM resource manager, which is related to the operating system's recovery termination management (RTM) and runs during termination processing.

- **Sync-point manager:** The sync-point manager coordinates changes to protected resources, so that all changes are made or no changes are made. The OS/390 sync-point manager is recoverable resource management services (RRMS). Three MVS components provide RRMS function; because resource recovery services (RRS) provides the sync-point services, most technical information uses RRS rather than RRMS.

If your resources are distributed, so that they are on multiple systems, the communication resource manager on one system will coordinate the changes. Each communication resource manager works with RRS on its system.

RRS can enable resource recovery on a single system or, with APPC/MVS, on multiple systems.

The application program, resource manager, and sync-point manager use a two-phase commit protocol to protect resources.

---

## Two-Phase Commit Protocol

The two-phase commit protocol is a set of actions used to make sure that an application program makes all changes to a collection of resources or makes no changes to the collection. The protocol makes sure of the **all-or-nothing changes** even if the system, RRS, or the resource manager fails.

The phases of the protocol are:

- **Phase 1:** In the first phase, each resource manager must be prepared to either commit or backout the changes. They prepare for the commit and tell RRS either YES, the change can be made, or NO, the change cannot be made.

First, RRS decides the results of the YES or NO responses from the resource managers. If the decision is YES to commit the changes, RRS hardens the decision, meaning that it stores the decision in an RRS log.

Once a commit decision is hardened, the application changes are considered committed. If there is a failure after this point, the resource manager will make the changes during restart. Before this point, a failure causes the resource manager to back out the changes during restart.

- **Phase 2:** In the second phase, the resource managers commit or back out the changes.

---

## Resource Recovery Process

For a look at the resource recovery process, think of a person who requests an automated teller machine (ATM) to transfer money from a savings account to a checking account. The application program receives the person's input from the ATM. Each account is in a different database. Each database has its own resource manager. The sync-point manager is RRS. Figure 10-1 shows how the ATM application, resource managers, and RRS work together

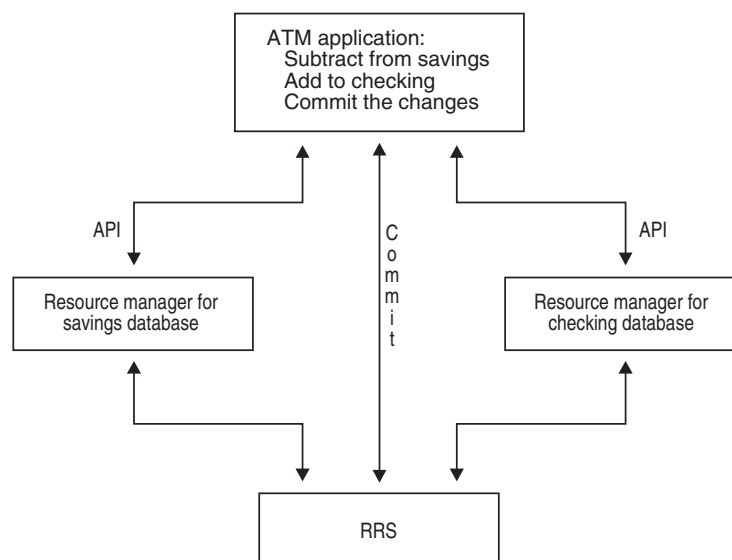

Figure 10-1. ATM Transaction

The actions required to process the ATM transaction are:

1. The ATM user requests transfer of money from a savings account to a checking account.
2. The ATM application program receives the ATM input.

Figure 10-2 shows, for the same transaction, the sequence of the following actions, with time moving from left to right, in the two-phase commit protocol RRS uses to commit the changes. The top line in the figure shows the two phases of the protocol described in “Two-Phase Commit Protocol” on page 10-2.

3. The ATM application requests the savings resource manager to subtract the money from the savings database. For this step, the application uses the resource manager’s application programming interface (API).
4. The ATM application requests the checking resource manager to add the money to the checking database. The application uses this resource manager’s API.
5. The ATM application issues a call to RRS to commit the database changes.
6. RRS asks the resource managers to prepare for the changes.
7. The resource managers indicate whether or not they can make the changes, by voting YES or NO. In Figure 10-2, both resource managers vote YES.
8. In response, RRS notifies the resource managers to commit the changes, that is, to make the changes permanently in the databases.
9. The resource managers complete the commit and return OK to RRS.
10. RRS gives a return code to the application program, indicating that all changes were made in the databases.

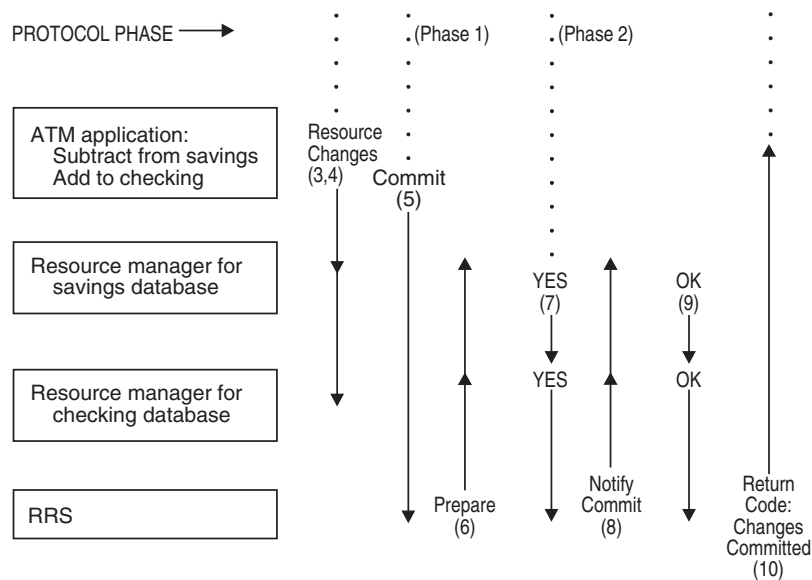

Figure 10-2. Two-Phase Commit Actions

If the ATM user decides not to transfer the money and presses a NO selection, the application requests backout, instead of commit, in step 6. In this case, the changes are backed out and are not actually made in any database. See Figure 10-3 on page 10-4.

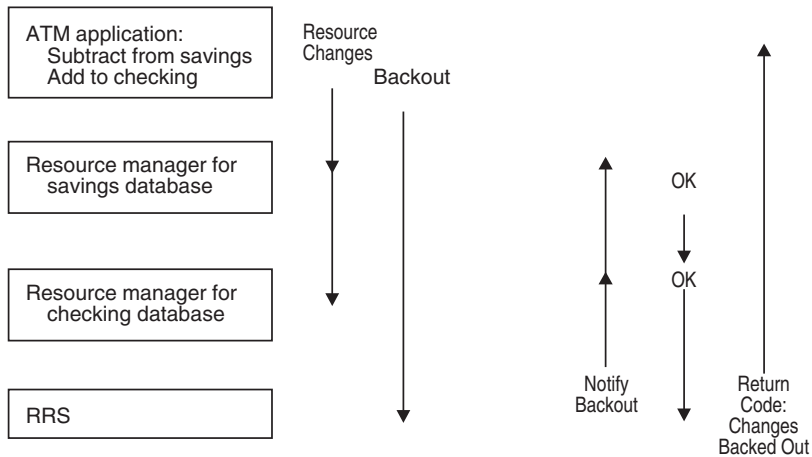

Figure 10-3. Backout — Application Request

Or if a resource manager cannot make the change to its database, the resource manager votes NO during prepare. If **any** resource manager votes NO, all of the changes are backed out. See Figure 10-4.

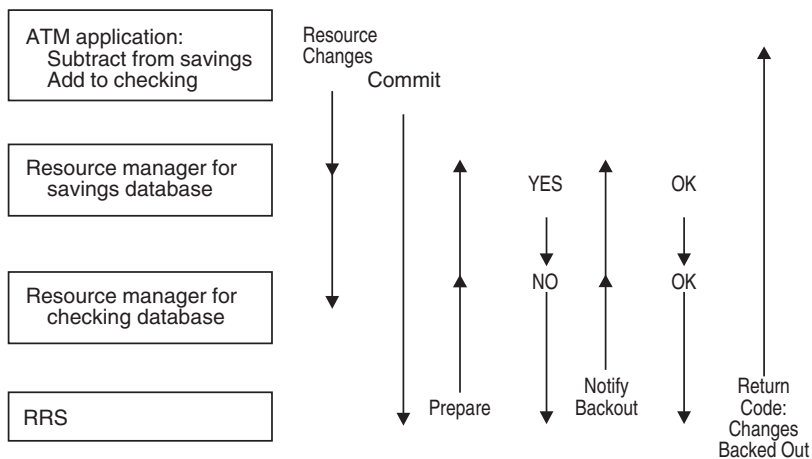

Figure 10-4. Backout — Resource Manager Votes NO

## Requesting Resource Protection and Recovery

To request resource protection, your application program must use resource managers that work with RRS to protect resources. The code in your application should do the following:

1. Request one or more accesses to resources for reads, writes, or both.
2. If all of the changes are to be made, request commit by issuing a call to the `Application_Commit_UR` service.
3. If none of the changes are to be made, request backout by issuing a call to the `Application_Backout_UR` service.

For details about the calls, see “`Application_Backout_UR (SRRBACK)`” on page 10-5 and “`Application_Commit_UR (SRRCMIT)`” on page 10-9.

---

## Using Distributed Resource Recovery

The databases for a work request may be distributed, residing on more than one system. In this case, the application program initiating the work uses a distributed communications manager, such as APPC/MVS, to request changes by an application program on another system. The database resource managers, communication resource managers, and RRS components work together to make or not make all changes of both application programs. Figure 10-5 illustrates distributed resource recovery.

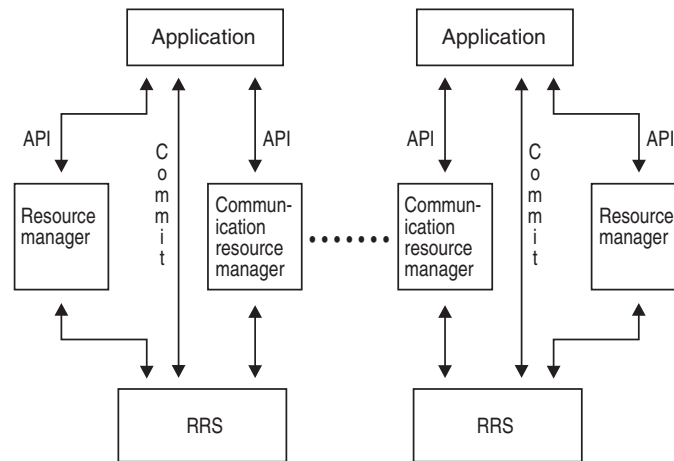

Figure 10-5. Transaction — Distributed Resource Recovery

---

## Application\_Backout\_UR (SRRBACK)

Call the Application\_Backout\_UR service to indicate that the changes for the unit of recovery (UR) are not to be made. A UR represents the application's changes to resources since the last commit or backout or, for the first UR, since the beginning of the application. In response to the call, RRS requests that the resource managers return their resources to the values they had before the UR was processed.

An application might need to issue a call to the Application\_Backout\_UR service if:

- An APPC/MVS call returns a TAKE\_BACKOUT return code. For example, a CI *send\_data* call to a communications manager could return TAKE\_BACKOUT.
- A resource manager call returns a return code that indicates that a resource manager directly backed out its resource. This situation can occur if the resource manager does not have the capability to return a TAKE\_BACKOUT code.
- A communications resource manager call returns a return code that indicates that a backout must be done, such as a return code of COM\_RESOURCE\_FAILURE\_NO\_RETRY from a CI call.

## Description

### Environment

The requirements for the caller are:

<b>Minimum authorization:</b>	Problem state, any PSW key
<b>Dispatchable unit mode:</b>	Task
<b>Cross memory mode:</b>	Any PASN, any HASN, any SASN

## Application\_Backout\_UR

<b>AMODE:</b>	24- or 31-bit
<b>ASC mode:</b>	Primary
<b>Interrupt status:</b>	Enabled for I/O and external interrupts
<b>Locks:</b>	No locks held
<b>Control parameters:</b>	Control parameters must be in the primary address space and addressable by the caller.
<b>Linkage:</b>	Standard MVS linkage conventions are used.

### Programming Requirements

The two methods described here can be used to access the callable service.

- Linkedit the stub routine ATRSCSS with the program that uses the service. ATRSCSS resides in SYS1.CSSLIB.
- Code the MVS LOAD macro within a program that uses the service to obtain the entry point address of the service. Use that address to call the service.

Additional language-specific statements may be necessary so that compilers can provide the proper assembler interface. Other programming notations, such as variable declarations, are also language-dependent.

SYS1.CSSLIB contains stubs for all of MVS's callable services including RRS. Other program products like DB2 and IMS also provide libraries that contain stubs for their versions of SRRBACK and SRRCMIT.

Because other program products like DB2 and IMS provide their own stubs for SRRBACK or SRRCMIT, you must make sure your program uses the correct stub. You need to take particular care when recompiling and linking any application that uses these services. When you linkedit, make sure that the data sets in the syslib concatenation are in the right order. For example, if you want a DB2 application to use the RRS callable service SRRBACK or SRRCMIT, you must ensure that SYS1.CSSLIB precedes the data sets with the stubs that DB2 provides for SRRBACK or SRRCMIT.

If you inadvertently cause your program to use SRRCMIT for RRS when it expects SRRCMIT for another program product like IMS, the application does not run correctly, and your program receives an error return code from the call to SRRCMIT.

For examples of the JCL link edit statements used with high-level languages, see "Chapter 4. Window Services Coding Examples" on page 4-1 or "Chapter 8. Reference Pattern Services Coding Examples" on page 8-1.

**High Level Language (HLL) Definitions:** The high level language (HLL) definitions for the callable service are:

HLL Definition	Description
ATRSASM	390 Assembler declarations
ATRSC	C/390 declarations
ATRSCOB	COBOL 390 declarations
ATRSPAS	Pascal 390 declarations
ATRSPLI	PL/I 390 declarations

**Assembler:** If you are an Assembler language caller running in AMODE 24, either use a BASSM instruction in place of the CALL or specify a LINKINST=BASSM parameter on the CALL macro. For example:

CALL SRRBACK(RETCODE),LINKINST=BASSM

**COBOL:** The return/reason code names and abend code names in ATRSCOB are truncated at 30 characters.

**PL/I:** The return/reason code names and abend code names in ATRSPLI are truncated at 31 characters.

**Restrictions:** The state of the UR must be **in-reset** or **in-flight**. A successful call creates a new UR that is **in-reset**.

The UR cannot be in local transaction mode.

**Input Register Information:** Before issuing the call, the caller does not have to place any information into any register unless using it in register notation for the parameter, or using it as a base register.

**Output Register Information:** When control returns to the caller, the GPRs contain:

Register	Contents
0-1	Used as work registers by the system
2-13	Unchanged
14	Used as a work register by the system
15	Return code

When control returns to the caller, the ARs contain:

Register	Contents
0-1	Used as work registers by the system
2-13	Unchanged
14-15	Used as work registers by the system

Some callers depend on register contents remaining the same before and after issuing a call. If the system changes the contents of registers on which the caller depends, the caller must save them before calling the service, and restore them after the system returns control.

**Performance Implications:** None.

**Syntax:** Write the call as shown in the syntax diagram. You must code the parameters in the CALL statement as shown.

CALL SRRBACK	(return_code)
--------------	---------------

**Parameters:** The parameters are explained as follows:

*return\_code*

- Returned parameter
- Character Set: N/A
- Length: 4 bytes

Contains the return code from the Application\_Backout\_UR service.

## Application\_Backout\_UR

**ABEND Codes:** The call might result in an abend X'5C4' with a reason code of X'00150000' through X'00150010'. See *OS/390 MVS System Codes* for the explanations and actions.

If your application ends abnormally during sync-point processing, the condition is called an asynchronous abend, and you might need to see the programmer at your installation responsible for managing RRS. Under information about working with application programs, *OS/390 MVS Programming: Resource Recovery* contains additional details about asynchronous abends.

Issuing SETRRS CANCEL for non-resource manager programs that use the synch-point service results in an abend X'058'. When RRS restarts, transactions that were in progress are resolved.

**Return Codes:** When the service returns control to your program, GPR 15 and *return\_code* contain a hexadecimal return code, shown in the following table. If you need help with a return code, see the programmer at your installation responsible for managing RRS. Under information about working with application programs, *OS/390 MVS Programming: Resource Recovery* contains additional details about these return codes.

Hexadecimal Return Code	Decimal Return Code	Meaning and Action
0	0	<b>Code:</b> RR_OK <b>Meaning:</b> Successful completion. The resource managers returned their resources to the values they had before the UR was processed. <b>Action:</b> None.
12D	301	<b>Code:</b> RR_BACKED_OUT_OUTCOME_PENDING <b>Meaning:</b> Environmental error. The backout was not completed, for one of the following reasons: <ul style="list-style-type: none"><li>• RRS requested that the resource managers back out the changes to the resources. However, the state of one or more of the resources is not known.</li><li>• RRS is not active.</li><li>• The resource manager fails with an incomplete protected interest in the UR, or RRS fails before the UR is complete.</li></ul> <b>Action:</b> The action by an application depends on the system environment. Some possible actions are: <ul style="list-style-type: none"><li>• Display a warning message to the end user.</li><li>• Write an exception entry into an output log.</li><li>• Abnormally end the application because the resource manager will not allow any further changes to the resource until the situation is resolved.</li></ul>
12E	302	<b>Code:</b> RR_BACKED_OUT_OUTCOME_MIXED <b>Meaning:</b> Environmental error. RRS requested that the resource managers back out the changes to the resources. However, one or more resources were changed. <b>Action:</b> Same as the action for return code 12D (301).

**Example:** In the pseudocode example, the application issues a call to request that RRS back out a UR.

```

:
:
CALL SRRBACK(RETCODE)
:
:

```

## Application\_Commit\_UR (SRRCMIT)

Call the Application\_Commit\_UR service to indicate that the changes for the unit of recovery (UR) are to be made permanent. A UR represents the application's changes to resources since the last commit or backout or, for the first UR, since the beginning of the application. In response to the call, RRS requests that the resource managers make the changes permanent.

Certain resource managers, such as a communications manager, can issue a TAKE\_COMMIT return code to an application that has requested changes to resources. In response to the TAKE\_COMMIT code from the resource manager, the application should request the changes to the resources:

- If all of the change requests are accepted, call the Application\_Commit\_UR service again.
- If any of the change requests are not accepted, call the Application\_Backout\_UR service to back out the changes.

### Description

**Environment:** The requirements for the caller are:

<b>Minimum authorization:</b>	Problem state, any PSW key
<b>Dispatchable unit mode:</b>	Task
<b>Cross memory mode:</b>	Any PASN, any HASN, any SASN
<b>AMODE:</b>	24- or 31-bit
<b>ASC mode:</b>	Primary
<b>Interrupt status:</b>	Enabled for I/O and external interrupts
<b>Locks:</b>	No locks held
<b>Control parameters:</b>	Control parameters must be in the primary address space and addressable by the caller.
<b>Linkage:</b>	Standard MVS linkage conventions are used.

**Programming Requirements:** The two methods described here can be used to access the callable service.

- Linkedit the stub routine ATRSCSS with the program that uses the service. ATRSCSS resides in SYS1.CSSLIB.
- Code the MVS LOAD macro within a program that uses the service to obtain the entry point address of the service. Use that address to call the service.

Additional language-specific statements may be necessary so that compilers can provide the proper assembler interface. Other programming notations, such as variable declarations, are also language-dependent.

SYS1.CSSLIB contains stubs for all of MVS's callable services including RRS. Other program products like DB2 and IMS also provide libraries that contain stubs for their versions of SRRBACK and SRRCMIT.

Because other program products like DB2 and IMS provide their own stubs for SRRBACK or SRRCMIT, you must make sure your program uses the correct stub.

## Application\_Commit\_UR

You need to take particular care when recompiling and linking any application that uses these services. When you linkedit, make sure that the data sets in the syslib concatenation are in the right order. For example, if you want a DB2 application to use the RRS callable service SRRBACK or SRRCMIT, you must ensure that SYS1.CSSLIB precedes the data sets with the stubs that DB2 provides for SRRBACK or SRRCMIT.

If you inadvertently cause your program to use SRRCMIT for RRS when it expects SRRCMIT for another program product like IMS, the application does not run correctly, and your program receives an error return code from the call to SRRCMIT.

For examples of the JCL link edit statements for high-level languages, see "Chapter 4. Window Services Coding Examples" on page 4-1 or "Chapter 8. Reference Pattern Services Coding Examples" on page 8-1.

*High Level Language (HLL) Definitions:* The high level language (HLL) definitions for the callable service are:

HLL Definition	Description
ATRSASM	390 Assembler declarations
ATRSC	C/390 declarations
ATRSCOB	COBOL 390 declarations
ATRSPAS	Pascal 390 declarations
ATRSPLI	PL/I 390 declarations

**Assembler:** If you are an Assembler language caller running in AMODE 24, either use a BASSM instruction in place of the CALL or specify a LINKINST=BASSM parameter on the CALL macro. For example:

```
CALL SRRCMIT(RETCODE),LINKINST=BASSM
```

**COBOL:** The return/reason code names and abend code names in ATRSCOB are truncated at 30 characters.

**PL/I:** The return/reason code names and abend code names in ATRSPLI are truncated at 31 characters.

**Restrictions:** The state of the UR that represents the changes must be **in-reset** or **in-flight**.

The UR cannot be in local transaction mode.

**Input Register Information:** Before issuing the call, the caller does not have to place any information into any register unless using it in register notation for the parameter, or using it as a base register.

**Output Register Information:** When control returns to the caller, the GPRs contain:

Register	Contents
0-1	Used as work registers by the system
2-13	Unchanged
14	Used as a work register by the system
15	Return code

When control returns to the caller, the ARs contain:

Register	Contents
0-1	Used as work registers by the system
2-13	Unchanged
14-15	Used as work registers by the system

Some callers depend on register contents remaining the same before and after issuing a call. If the system changes the contents of registers on which the caller depends, the caller must save them before calling the service, and restore them after the system returns control.

**Performance Implications:** None.

**Syntax:** Write the call as shown in the syntax diagram. You must code the parameter in the CALL statement as shown.

CALL SRRCMIT	(return_code)
--------------	---------------

**Parameters:** The parameters are explained as follows:

- return\_code*
- Returned parameter
    - Type: Integer
    - Length: 4 bytes

Contains the return code from the Application\_Commit\_UR service.

**ABEND Codes:** The call might result in an abend X'5C4' with a reason code of X'00160000' through X'00160012'. See *OS/390 MVS System Codes* for the explanations and actions.

If your application ends abnormally during sync-point processing, the condition is called an asynchronous abend, and you might need to see the programmer at your installation responsible for managing RRS. Under information about working with application programs, *OS/390 MVS Programming: Resource Recovery* contains additional details about asynchronous abends.

Issuing SETRRS CANCEL for non-resource manager programs that use the synch-point service results in an abend X'058'. When RRS restarts, transactions that were in progress are resolved.

**Return Codes:** When the service returns control to your program, GPR 15 and *return\_code* contain a hexadecimal return code, shown in the following table. If you need help with a return code, see the programmer at your installation responsible for managing RRS. Under information about working with application programs, *OS/390 MVS Programming: Resource Recovery* contains additional details about these return codes.

Hexadecimal Return Code	Decimal Return Code	Meaning and Action
0	0	<p><b>Code:</b> RR_OK</p> <p><b>Meaning:</b> Successful completion. The changes to all protected resources have been made permanent.</p> <p><b>Action:</b> None.</p>

## Application\_Commit\_UR

Hexadecimal Return Code	Decimal Return Code	Meaning and Action
65	101	<p><b>Code:</b> RR_COMMITTED_OUTCOME_PENDING</p> <p><b>Meaning:</b> Environmental error. The commit was not completed:</p> <ul style="list-style-type: none"> <li>• RRS requested that the resource managers make the changes to the resources permanent. However, the state of one or more of the resources is not known.</li> </ul> <p><b>Action:</b> The action by an application depends on the system environment. Some possible actions are:</p> <ul style="list-style-type: none"> <li>• Display a warning message to the end user.</li> <li>• Write an exception entry into an output log.</li> <li>• Abnormally end the application because the resource manager will not allow any further changes to the resource until the situation is resolved.</li> </ul>
66	102	<p><b>Code:</b> RR_COMMITTED_OUTCOME_MIXED</p> <p><b>Meaning:</b> Environmental error. RRS requested that the resource managers make the changes to the resources permanent. One or more resources were changed, but one or more were not changed.</p> <p><b>Action:</b> Same as the action for return code 65 (101).</p>
C8	200	<p><b>Code:</b> RR_PROGRAM_STATE_CHECK</p> <p><b>Meaning:</b> Environmental error. The commit failed. The resource managers did not make the changes to the resources because one of the following occurred:</p> <ul style="list-style-type: none"> <li>• A resource on the same system as the application is not in the proper state for a commit.</li> <li>• A protected conversation is not in the required state: <b>send, send pending, defer receive, defer allocate, sync_point, sync_point send, sync_point deallocate.</b></li> <li>• A protected conversation is in <b>send</b> state. The communications manager started sending the basic conversation logical record, but did not finish sending it.</li> </ul> <p><b>Action:</b> Initiate an action by a resource manager to get its resource to a committable state, then call Application_Commit_UR again. For example, if the application has allocated a protected conversation through APPPC/MVS, and the conversation is in receive state, the application gets this return code. It then must use APPC/MVS services to change the conversation to send state before issuing the commit request again.</p>
12C	300	<p><b>Code:</b> RR_BACKED_OUT</p> <p><b>Meaning:</b> Environmental error. The commit failed. The resource managers backed out the changes, returning the resources to the values they had before the UR was processed.</p> <p><b>Action:</b> Same as the action for return code 65 (101).</p>

## Application\_Commit\_UR

Hexadecimal Return Code	Decimal Return Code	Meaning and Action
12D	301	<p><b>Code:</b> RR_BACKED_OUT_OUTCOME_PENDING</p> <p><b>Meaning:</b> Environmental error. The commit failed for one of the following reasons:</p> <ul style="list-style-type: none"><li>• RRS requested that the resource managers back out the changes to the resources. However, the state of one or more of the resources is not known.</li><li>• RRS is not active.</li></ul> <p><b>Action:</b> Same as the action for return code 65 (101).</p>
12E	302	<p><b>Code:</b> RR_BACKED_OUT_OUTCOME_MIXED</p> <p><b>Meaning:</b> Environmental error. The commit failed. RRS requested that the resource managers back out the changes to the resources. One or more resources were backed out, but one or more were changed.</p> <p><b>Action:</b> Same as the action for return code 65 (101).</p>

**Example:** In the pseudocode example, the application issues a call to request that RRS commit a UR.

```
⋮  
CALL SRRCMIT(RETCODE)  
⋮
```

## Chapter 11. IEAAFFN — Assign Processor Affinity for Encryption or Decryption

Call IEAAFFN when the only function performed by your program is to encrypt or decrypt data. Encryption and decryption take place on processors that have Integrated Cryptographic Features (ICRFs) associated with them. IEAAFFN assigns a program affinity to processors with an ICRF; that is, IEAAFFN makes sure the system runs your program on a processor that has an ICRF associated with it.

You do **not** have to use the IEAAFFN service to ensure the system runs a program on a processor with an ICRF; the system ensures that automatically. However, you can avoid some of the system overhead involved in the selection process by using the IEAAFFN service. IBM recommends that you use the service in programs whose **only** function is encryption or decryption.

**Note:** When you use this service to either establish or remove processor affinity for a program, the program permanently loses any processor affinity that the system programmer assigned to it in the SCHEDxx member of SYS1.PARMLIB.

Code the CALL following the syntax of the high level language you are using and specifying all parameters in the order shown below.

CALL IEAAFFN	(feature ,operation_type ,return_code)
--------------	--

The parameters are explained as follows:

**feature**

Specifies the feature required by your program. Specify CRYPTO to indicate an ICRF.

Define *feature* as character data of length 10. Pad the string on the right with 4 blanks.

**,operation\_type**

Specifies the type of action you want to take. The types are:

**GRANT**            Establish affinity for the program to processors with an ICRF.

**REMOVE**          Remove affinity for the program to processors with an ICRF.

**Note:** After you issue a REMOVE request, the program has no processor affinity; it can run on any processor.

Define *operation\_type* as character data of length 6. If you specify GRANT, pad the string on the right with 1 blank.

**,return\_code**

When IEAAFFN completes, *return\_code* contains the return code from the service. The return code value is also in register 15.

Define *return\_code* as integer data of length 4. The return codes are explained under "Return Codes".

---

## Restrictions and Limitations

Use the IEAAFFN service to request affinity to processors with an ICRF only for sections of a program that require an ICRF and not other features, such as a Vector Facility.

---

## Requirements

<b>Authorization:</b>	Supervisor state or Problem state, any PSW key
<b>Dispatchable unit mode:</b>	Task
<b>Cross memory mode:</b>	You can be either in cross memory mode or not
<b>AMODE:</b>	24- or 31-bit
<b>ASC mode:</b>	Primary
<b>Interrupt status:</b>	Enabled for I/O and external interrupts
<b>Locks:</b>	None held
<b>Control parameters:</b>	Must be in the primary address space

---

## Return Codes

When IEAAFFN returns control to your program, *return\_code* and register 15 contain a return code. The following table identifies the return codes in hexadecimal and decimal (in parentheses), tells what each means, and recommends an action that you should take.

Table 11-1. IEAAFFN Return Codes

Return code	Meaning and Action
00000000 (0)	<b>Meaning:</b> The operation was successful. <b>Action:</b> None required.
00000004 (4)	<b>Meaning:</b> The program already had processor affinity assigned to it by the system programmer. The system replaces that affinity with the affinity you requested in this service. <b>Action:</b> None required.
0000000C (12)	<b>Meaning:</b> Your program was not running in task mode. <b>Action:</b> This service is not available to SRB mode programs. See the FEATURE= option on the SCHEDULE macro for the use of this function in SRB mode.
00000010 (16)	<b>Meaning:</b> The feature you specified was not a valid feature. <b>Action:</b> Specify a valid feature name.
00000014 (20)	<b>Meaning:</b> The operation type you specified was not valid. <b>Action:</b> Specify a valid operation type.
00000018 (24)	<b>Meaning:</b> The feature you specified is not installed on any of the processors in the system. <b>Action:</b> To the system programmer: See that the program runs on a system with the feature installed.

Table 11-1. IEAAFFN Return Codes (continued)

Return code	Meaning and Action
000001C (28)	<p><b>Meaning:</b> A system error has occurred.</p> <p><b>Action:</b> To the system programmer: The error is recorded in LOGREC. Look for a record with a subcomponent of "IEAAFFN CSS"; then call your IBM Support Center.</p>

---

## Chapter 12. CSRL16J — Transfer Control to Another Routine

The CSRL16J service allows you to transfer control to another routine running under the same request block (RB) as the calling program. The CSRL16J service will transfer control with the contents of all 16 registers intact. When you transfer control to the other routine, use the CSRL16J service to:

- Define the entry characteristics and register contents for the target routine.
- Optionally free dynamic storage associated with the calling program.

When the service is successful, control transfers to the target routine. After the target routine runs, it can transfer control to any program running under the same request block (RB), including the calling program.

The CSRL16J service returns control to the calling program **only** when it cannot transfer control successfully to the target because of an error.

---

### Defining the Entry Characteristics of the Target Routine

Specify the entry characteristics for the target in data area L16J, which forms the parameter list passed from the calling program to CSRL16J. Use the CSRYL16J mapping macro to see the format of the L16J parameter list. To build the L16J parameter list, first initialize the parameter list with zeroes and then fill in the desired fields. This ensures that all fields requiring zeroes are correct. You can specify the following characteristics for the target in L16J:

- Length of the L16J parameter list, L16JLENGTH field in mapping macro CSRYL16J.
- Contents of the general purpose registers (GPRs) 0-15, L16JGRS field in mapping macro CSRYL16J.
- Contents of the access registers (ARs) 0-15, L16JARS field in mapping macro CSRYL16J.
- PSW information for the target routine, field L16JPSW field in mapping macro CSRYL16J.
  - PSW address and AMODE
  - PSW ASC mode - primary or AR
  - PSW program mask
  - PSW condition code

Authorized callers, (callers in supervisor state, with PSW key 0-7, or with a PKM that allows any key 0-7) can specify:

- PSW state - problem or supervisor
- PSW key.

For unauthorized callers, the system uses the PSW state and key of the calling program for the target routine.

See *Principles of Operation* for more information about the contents of the PSW.

- Bit indicating whether or not you want to specify the contents of the access registers (ARs) for the target routine. This is the L16JPROCESSARS bit in mapping macro CSRYL16J.

Set the bit on if you want to specify the contents of the ARs. If you set the bit off, the system determines the contents of the ARs.

If the bit is set on when CSRL16J passes control to the target routine, the access registers (ARs) contain:

Register	Contents
0-15	Specified by the caller

If the bit is set off when CSRL16J passes control to the target routine, the access registers (ARs) contain:

Register	Contents
0-1	Do not contain any information for use by the routine
2-13	The contents are the same as they were when the caller issued the CSRL16J service.
14-15	Do not contain any information for use by the routine

---

## Freeing Dynamic Storage Associated with the Caller

If the calling program has a dynamic storage area associated with it, you can specify that some or all of this storage area be freed before CSRL16J transfers control to the target. In the L16J parameter list, specify:

- The subpool of the area that you want the system to free. L16JSUBPOOL field in mapping macro CSRYL16J.
- The length, in bytes, of the dynamic storage area you want the system to free. L16JLENGHTHOFREE field in mapping macro CSRYL16J.
- The address of the dynamic storage area you want the system to free. L16JAREATOFREE field in mapping macro CSRYL16J.

Make sure that the address is on a double-word boundary. Otherwise the service ends with an abend code X'978'. See *OS/390 MVS System Codes* for information on abend code X'978'.

The system frees the storage only when the CSRL16J service is successful.

---

## Programming Requirements

These are the requirements:

- The calling program must be in 31-bit addressing mode.
- Before you use the CSRL16J service, you must build a parameter list, L16J, to pass to the service. The parameter list includes the entry characteristics and environment for the target.

If you are coding in C/370, you can include the CSRLJC macro to provide declarations in the calling program for the L16J parameter area and return codes. See Figure 12-1 on page 12-3.

If you are coding in PL/I, you can include the CSRLJPLI macro to provide declarations for the return codes only. See Figure 12-2 on page 12-5 for the CSRLJPLI macro. Use the data area, mapped by the CSRYL16J mapping macro, as a model for the structure of your parameter list when coding in PL/I.

**CSRLJC provides the following declarations for use in your C/370 program:**

```

/*****
 *      Type Definitions for User Specified Parameters      *
 *****/

/* Type for user supplied L16J */
typedef struct ??<
int Version; /* Must be 0 */
int Length; /* Initialize to CSRL16J_LENGTH */
int SubPool; /* Subpool of storage to be freed */
union ??<
char GRs??(64??); /* General registers */
int GR??(16??); /* General register 0-15 */
??> u1;
union ??<
char ARs??(64??); /* Access registers */
int AR??(16??); /* Access register 0-15 */
??> u2;
union ??<
char PSW??(8??); /* PSW: the processing will use the address,
AMODE, ASC mode, CC, and program mask. For a
supervisor state or PKM 0-7 or key 0-7
caller, it will use the state and key from
the PSW. Otherwise, it will set to caller
key and state. */
struct ??<
int PSWByte0to3 : 32; /* First 4 bytes */
union ??<
void *PSWAddr; /* Address and AMODE */
struct ??<
int PSWAmode : 1; /* AMODE */
int Rsvd0 : 31;
??> s2;
??> u4;
??> s1;
??> u3;
union ??<
struct ??<
int Flags : 8; /* Flags */
int Rsvd0 : 24; /* Reserved */
??> s3;
struct ??<
int ProcessARs : 1; /* If on, ARs will be processed. Otherwise
not. If not processed, ARs 0, 1, 14, and 15 are
unpredictable. ARs 2-13 are taken from the values
present when the service is entered. */
int Rsvd0 : 31; /* Reserved */
??> s4;
??> u5;

```

Figure 12-1. CSRLJC declarations for the L16J parameter list for C/370 (Part 1 of 2)

```

void *AreaToFree; /* Address of area to free. If this is non-0
                  then the area will be freed using the subpool
                  specified in L16J.Subpool. This can be used
                  to free the caller's entire dynamic area if
                  so desired. When this option is specified, it
                  is necessary that the area begin on a
                  doubleword boundary. */

Figure 12-2. CSRLJPLI declarations for return codes for PL/I

---

## Restrictions

None.

---

## Performance Implications

None.

---

## Syntax Diagram

Code the invocation following the syntax of the language you are using. Specify parameters in the order shown.

## C/370 Syntax

csrl16j	(&L16J ,&return_code)
---------	--------------------------

## PL/I Syntax

CALL CSRL16J	(L16J ,return_code)
--------------	------------------------

---

## Parameters

The parameters are explained as follows:

### L16J

Specifies a parameter list that the service uses to define the entry characteristics and environment for the target.

### return\_code

When the service completes, *return\_code* contains the return code.

---

## Return Codes

If the CSRL16J service returns control to the caller, an error has occurred and the service was unable to transfer control to the target routine. In this case, the return code is always nonzero. When the service successfully transfers control to the target routine, the return code is zero.

Return codes from the CSRL16J service are as follows:

Table 12-1. CSRL16J Return Codes

Return Code (hexadecimal)	Meaning and Action
00	<b>Meaning:</b> Successful completion. The calling program will never see this return code because it indicates that the target routine received control. <b>Action:</b> None.
04	<b>Meaning:</b> The value specified in the L16JVERSION field of the L16J data area was not a zero. The L16JVERSION field must contain a value of zero. <b>Action:</b> When you build the L16J data area, first zero the entire L16J data area and then fill in the required fields. This process ensures that all fields that must contain zeroes are correct.
08	<b>Meaning:</b> The calling program was not in 31-bit addressing mode, which is required. <b>Action:</b> Make sure the calling program is in 31-bit addressing mode.
0C	<b>Meaning:</b> One of the fields in the L16J data area that is reserved for IBM use contained a nonzero value. Any field reserved for IBM use must contain a value of zero. <b>Action:</b> When you build the L16J data area, first zero the entire L16J data area and then fill in the required fields. This process ensures that all fields that must contain zeroes are correct.
10	<b>Meaning:</b> The value specified in field L16JLENGTH in the L16J data area was less than the actual length of the L16J. <b>Action:</b> Make sure that the value in the L16JLENGTH field reflects the actual length of the L16J data area.

Table 12-1. CSRL16J Return Codes (continued)

Return Code (hexadecimal)	Meaning and Action
18	<p><b>Meaning:</b> The PSW provided in field L16JPSW of the L16J data area specified an incorrect ASC mode.</p> <p><b>Action:</b> In the L16JPSW field, specify either primary or AR ASC mode.</p>

## Example

The following example, coded in C/370 uses CSRL16J to transfer control to a C/370 program. The target routine executes in the mode and with the register contents specified by the calling program in the L16J parameter list.

This example performs the following operations:

- Fills in L16J parameter list with PSW and execution mode data.
- Calls an assembler routine to obtain the current register contents of registers 0 through 13 and copies them to the L16J parameter list.
- Defines the contents of registers 14 and 15 for the target routine.
- Issues setjmp to allow return from the target routine.
- Invokes the C/370 function L16JPrg through CSRL16J.
- CSRL16J issues longjmp to return to caller and complete processing.

To use this example, you must also use the assembler program following the C/370 example.

## C/370 Example Program

```
#include <stdlib.h>
#include <stdio.h>
#include <string.h>
#include <setjmp.h>
#include "CSRLJC.H"

#define FALSE 0
#define TRUE 1

/* REG0T013 is the assembler assist routine (below) to extract
   registers 0 through 13, for C/370 addressability */
#pragma linkage(REG0T013,OS)

int      rcode;
int      i;
unsigned int regs??(14??); /* Register save area */
jmp_buf  JumpBuffer; /* Buffer for setjmp/longjmp */
L16J     L16JParmArea; /* L16J parameter list structure */

/* Function prototype for function to be called via L16J */
void L16JPrg();

/* Invoke a C/370 function via L16J Callable Services */
main()
{
    /* Start by initializing the entire L16J parameter list */
    memset(&L16JParmArea,'\0',sizeof(L16J));

    /* The following fields were implicitly initialized to zero
       by the preceding statement:
       L16JParmArea.Version
```

```

        L16JParmArea.SubPool
        L16JParmArea.AreaToFree
        L16JParmArea.LengthToFree
        These field do not need to be explicitly set unless a value
        other than zero is required */

/* Place parameter list length size into parameter list */
L16JParmArea.Length = sizeof(L16J);

/* Create a Problem State/Key 8 PSW */
L16JParmArea.u3.s1.PSWByte0to3 = 0x078D1000;
L16JParmArea.u3.s1.u4.PSWAddr = (void *) &L16JPrg;

/* Mode data */
L16JParmArea.u3.s1.u4.s2.PSWAmode = 1;
L16JParmArea.u5.s4.ProcessARs = 1;

/* Call assembler assist routine to obtain current register
   values */
REG0T013(&regs);

/* Place register values into parameter list */
for (i=0;i<14;i++)
    L16JParmArea.u1.GR??(i??)= regs??(i??);

/* Register 14 is not being used in this linkage, but we
   have set it to zero for this example */
L16JParmArea.u1.GRAddr??(14??) = 0;

/* Set register 15 for entry to routine */
L16JParmArea.u1.GRAddr??(15??) = (void *) &L16JPrg;

printf("L16JC - Call L16J to invoke L16JPrg\n");

/* Use setjmp to allow return to this point in program. If
   setjmp is being called for the first time, invoke L16JPrg
   via L16J Callable Services. If returning from longjmp,
   skip call to L16J services and complete processing. */
if (!setjmp(JumpBuffer))
{
    csr116j (&L16JParmArea,&rcode);

    /* Demonstrate use of L16J C/370 declares */
    switch (rcode)
    {
        /* Select on a particular return code value */
        case CSRL16J_BAD_PSW:
            printf("L16JC - L16J unsuccessful, bad PSW\n");
            break;
        /* Default error processing */
        default:
            printf("L16JC - L16J unsuccessful, RC = %d\n",rcode);
            break;
    }
}
printf("L16JC - Returned from L16JPrg\n");
}

/* The routine below receives control via L16J Callable Services.
   control is passed back to main via longjmp. */
void L16JPrg(void)
{
    printf("L16JC - L16JPrg got control\n");
    longjmp(JumpBuffer,1);
}

```

## Assembler program for use with the C/370 example

To use this example you must assemble the following program and link it with the C/370 program above.

```
SR0T013 CSECT
SR0T013 AMODE 31
SR0T013 RMODE ANY
*
* Assembler assist routine to save contents of registers 0 through 13
* to the area pointed to by register 1.
*
REG0T013 DS    0H
          ENTRY REG0T013
* Get address of the save area
          L     15,0(,1)
* Save registers 0 to 13
          STM   0,13,0(15)
* Return to the caller
          BR    14
          END   SR0T013
```

---

## Chapter 13. CSRSI — System Information Service

Use the CSRSI service to retrieve system information. You can request information about the machine itself, the logical partition (LPAR) in which the machine is running, or the virtual machine hypervisor (VM) under which the system is running. The returned information is mapped by DSECTs in macro CSRSIIDF (for assembler language callers) or structures in header file CSRSIC (for C language callers).

The information available depends upon the availability of the Store System Information (STSI) instruction. When the STSI instruction is not available (which would be indicated by receiving the return code 4 (equate symbol CSRSI\_ST SINOTAVAILABLE), only the SI00PCCACPID, SI00PCCACPUA, and SI00PCCACAFM fields within the returned infoarea are valid. When the STSI instruction is available, the validity of the returned infoarea depends upon the system:

- If the system is running neither under LPAR nor VM, then only the CSRSI\_Request\_V1CPC\_Machine data are valid.
- If the system is running under a logical partition (LPAR), then both the CSRSI\_Request\_V1CPC\_Machine data and CSRSI\_Request\_V2CPC\_LPAR data are valid.
- If the system is running under a virtual machine hypervisor (VM), then all of the data (CSRSI\_Request\_V1CPC\_Machine, CSRSI\_Request\_V2CPC\_LPAR, and CSRSI\_Request\_V3CPC\_VM) are valid.

You can request any or all of the information regardless of your system, and validity bits will indicate which returned areas are valid.

---

### Description

### Environment

The requirements for the caller are:

<b>Minimum authorization:</b>	Problem state, key 8–15
<b>Dispatchable unit mode:</b>	Task or SRB
<b>Cross memory mode:</b>	Any PASN, any HASN, any SASN
<b>AMODE:</b>	24- or 31-bit when using the CALL CSRSI form (or csrsi in C), 31-bit when using an alternate form
<b>ASC mode:</b>	Primary
<b>Interrupt status:</b>	Enabled or disabled for I/O and external interrupts
<b>Locks:</b>	The caller may hold a LOCAL lock, the CMS lock, or the CPU lock but is not required to hold any locks.

### Programming Requirements

The caller should include the CSRSIIDF macro to map the returned information and to provide equates for the service.

### Restrictions

None

### Input Register Information

The caller is not required by the system to set up any registers.

## System Information Service (CSRSI)

### Output Register Information

When control returns to the caller, the GPRs contain:

Register	Contents
0-1	Used as work registers by the system
2-13	Unchanged
14-15	Used as work registers by the system

### Syntax

CALL CSRSI,	(Request ,Infoarealen ,Infoarea ,Returncode)
-------------	---

**In C:** the syntax is similar. You can use either of the following techniques to invoke the service:

1. CSRSI (Request,...Returncode);  
When you use this technique, you must link edit your program with a linkage-assist routine (also called a stub) in SYS1.CSSLIB.
2. CSRSI\_byaddr (Request,...Returncode);  
This second technique requires AMODE=31, and, before you issue the CALL, you must verify that the CSRSI service is available (in the CVT, both CVTOSEXT and CVTCSRSI bits are set on).

**In Assembler:** Link edit your program with a linkage-assist routine (also called a stub) in SYS1.CSSLIB unless you use either of the following techniques as an alternative to CALL CSRSI:

1. LOAD EP=CSRSI  
Save the entry point address  
...  
Put the saved entry point address into R15  
Issue CALL (15),...
2. L 15,X'10' Get CVT  
L 15,X'220'(.15)  
L 15,X'30'(.15) Get address of CSRSI  
CALL (15),(...)

Both of these techniques require AMODE=31. If you use the second technique, before you issue the CALL, you must verify that the CSRSI service is available (in the CVT, both CVTOSEXT and CVTCSRSI bits are set on).

### Parameters

#### Request

Supplied parameter:

- Type: Integer
- Length: Full word

Request identifies the type of system information to be returned. The field must contain a value that represents one or more of the possible request types. You add the values to create the full word. Do not specify a request more than once. The possible requests, and their meanings, are:

#### CSRSI\_Request\_V1CPC\_Machine

The system is to return information about the machine.

## System Information Service (CSRSI)

### CSRSI\_Request\_V2CPC\_LPAR

The system is to return information about the logical partition (LPAR).

### CSRSI\_Request\_V3CPC\_VM

The system is to return information about the virtual machine (VM).

#### ,Infoarealen

Supplied parameter:

- Type: Integer
- Range: X'1040', X'2040', X'3040', X'4040'
- Length: Full word

Infoarealen specifies the length of the infoarea parameter.

#### ,Infoarea

Returned parameter:

- Type: Character
- Length: X'1040', X'2040', X'3040', X'4040' bytes

Infoarea is to contain the retrieved system information. (Infoarealen specifies the length of the provided area.) The infoarea must be of the proper length to hold the requested information. This length depends on the value of the Request parameter.

- When the Request parameter is CSRSI\_Request\_V1CPC\_Machine, the returned infoarea is mapped by SIV1 and the infoarealen parameter must be X'2040'.
- When the Request parameter is CSRSI\_Request\_V1CPC\_Machine plus CSRSI\_Request\_V2CPC\_LPAR, the returned infoarea is mapped by SIV1V2 and the infoarealen parameter must be X'3040'.
- When the Request parameter is CSRSI\_Request\_V1CPC\_Machine plus CSRSI\_Request\_V2CPC\_LPAR plus CSRSI\_Request\_V3CPC\_VM, the returned infoarea is mapped by SIV1V2V3 and the infoarealen parameter must be X'4040'.
- When the Request parameter is CSRSI\_Request\_V1CPC\_Machine plus CSRSI\_Request\_V3CPC\_VM, the returned infoarea is mapped by SIV1V3 and the infoarealen parameter must be X'3040'.
- When the Request parameter is CSRSI\_Request\_V2CPC\_LPAR, the returned infoarea is mapped by SIV2 and the infoarealen parameter must be X'1040'.
- When the Request parameter is CSRSI\_Request\_V2CPC\_LPAR plus CSRSI\_Request\_V3CPC\_VM, the returned infoarea is mapped by SIV2V3 and the infoarealen parameter must be X'2040'.
- When the Request parameter is CSRSI\_Request\_V3CPC\_VM, the returned infoarea is mapped by SIV3 and the infoarealen parameter must be X'1040'.

#### ,Returncode

Returned parameter:

- Type: Integer
- Length: Full word

Returncode contains the return code from the CSRSI service.

## Return Codes

When the CSRSI service returns control to the caller, Returncode contains the return code. To obtain the equates for the return codes:

- If you are coding in assembler, include mapping macro CSRSIIDF, described in *OS/390 MVS Data Areas, Vol 2 (DCCB-ITZYRETC)*.

## System Information Service (CSRSI)

- If you are coding in C, use include file CSRSIC. See Figure 13-1 on page 13-5.

The following table describes the return codes, shown in decimal.

Return Code and Equate Symbol	Meaning and Action
00 (0) CSRSI_SUCCESS	<b>Meaning:</b> The CSRSI service completed successfully. All information requested was returned. <b>Action:</b> Check the si00validityflags field to determine the validity of each returned area.
04 (4) CSRSI_ST SINOTAVAILABLE	<b>Meaning:</b> The CSRSI service completed successfully, but since the Store System Information (STSI) instruction was not available, only the SI00PCCACPID, SI00PCCACPUA, and SI00PCCACAFM fields are valid. <b>Action:</b> None required.
08 (8) CSRSI_SERVICENOTAVAILABLE	<b>Meaning:</b> Environmental error: The CSRSI service is not available on this system. <b>Action:</b> Avoid calling the CSRSI service unless running on a system on which it is available.
12 (C) CSRSI_BADREQUEST	<b>Meaning:</b> User error: The request parameter did not specify a word formed from any combination of CSRSI_Request_V1CPC_Machine, CSRSI_Request_V2CPC_LPAR, and CSRSI_Request_V3CPC_VM. <b>Action:</b> Correct the parameter.
16 (10) CSRSI_BADINFOAREALEN	<b>Meaning:</b> User error: The Infoarealen parameter did not match the length of the area required to return the requested information. <b>Action:</b> Correct the parameter.
20 (14) CSRSI_BADLOCK	<b>Meaning:</b> User error: The service was called while holding a system lock other than CPU, LOCAL/CML, or CMS. <b>Action:</b> Avoid calling in this environment.

---

## CSRSIC C/370 Header File

For the C programmer, include file CSRSIC provides equates for return codes and data constants, such as Register service request types. To use CSRSIC, copy the file from SYS1.SAMPLIB to the appropriate local C library. The contents of the file are displayed in Figure 13-1 on page 13-5.

The licensed program described in this information and all licensed material available for it are provided by IBM under terms of the IBM Customer Agreement, IBM International Program License Agreement, or any equivalent agreement between us.

If you are viewing this information softcopy, the photographs and color illustrations may not appear.

This information contains examples of data and reports used in daily business operations. To illustrate them as completely as possible, the examples include the names of individuals, companies, brands, and products. All of these names are fictitious and any similarity to the names and addresses used by an actual business enterprise is entirely coincidental.

### COPYRIGHT LICENSE:

This information contains sample application programs in source language, which illustrates programming techniques on various operating platforms. You may copy, modify, and distribute these sample programs in any form without payment to IBM, for the purposes of developing, using, marketing or distributing application programs conforming to the application programming interface for the operating platform for which the sample programs are written. These examples have not been thoroughly tested under all conditions. IBM, therefore, cannot guarantee or imply reliability, serviceability, or function of these programs. You may copy, modify, and distribute these sample programs in any form without payment to IBM for the purposes of developing, using, marketing, or distributing application programs conforming to IBM's application programming interfaces.

---

## Programming Interface Information

This book is intended to help the customer to write applications that use operating system services. This book documents General-use Programming Interface and Associated Guidance Information provided by OS/390.

General-use programming interfaces allow the customer to write programs that obtain the services of OS/390.

# Glossary

The glossary defines terms as they are used in this book.

## D

**data object.** (1) A VSAM linear data set. (2) A storage area, outside the user's storage, that window services defines as a temporary object.

**data-in-virtual.** An MVS facility that enables a user to access a data object as though that data object resided in the user's storage.

## G

**gap.** The grouping of consecutive bytes that the program repeatedly skips over. When a reference pattern has a gap, gaps and reference units alternate throughout the data area. See also *reference pattern* and *reference unit*.

## H

**hiperspace.** A range of up to two gigabytes of virtual storage that a program can use like a buffer.

## L

**linear data set.** A type of VSAM data set where data is stored as a linear string of bytes.

## M

**mapping.** A process where window services makes a data object or part of a data object accessible to a user program through a scroll area or through a window.

## O

**object.** See data object.

## P

**permanent data object.** A virtual storage access method (VSAM) linear data set that resides on DASD (also called a data-in-virtual object).

## R

**reference pattern.** The order in which a program's instructions process a data structure, such as an array. A reference pattern can be sequential or random and can contain gaps.

**reference unit.** A grouping of consecutive bytes that the program references. If the reference pattern has a gap, the reference unit is the grouping of bytes between gaps; gaps and reference units alternate throughout the data area. If the reference pattern does not have gaps, the reference unit is a logical grouping according to the structure of the data.

## S

**scroll area.** An area of expanded storage that window services obtains. For a permanent object, window services maps a window to the scroll area and maps the scroll area to the permanent data object. You can use the scroll area to make interim changes to a permanent data object. For a temporary data object, the scroll area is the data object. Window services maps the window to the scroll area.

**scrolling.** A process where window services saves changes that a user has made in a window. For a permanent data object, window services saves the changes in the scroll area, without updating the permanent object. For a temporary object, window services updates the temporary object.

## T

**temporary data object.** An area of expanded storage that window services provides for use by your program. You can use this storage to hold temporary data instead of using a DASD workfile. Window services provides no means for you to save a temporary data object.

## V

**VSAM.** Virtual storage access method.

## W

**window.** An area in the user's storage where the user can view or change data in a data object that window services has made available.

# Index

## A

- access to a data object
  - permanent object 1-6
  - temporary object 1-7
- access to an object
  - terminating 2-12
- ADA programming language
  - example using window services 4-1
- application
  - in resource recovery 10-1
- application\_backout\_UR call 10-5
  - return and reason codes 10-8
  - syntax 10-7
- application\_commit\_UR call 10-9
  - return and reason codes 10-11
  - syntax 10-11

## B

- back out changes to protected resources 10-5
- blocks of an object
  - definition 1-1
  - identifying blocks to be viewed 2-6
  - size 1-1
  - updating blocks 2-9
  - updating blocks in a temporary object 2-8

## C

- C programming language
  - call syntax for latch manager services 9-1
  - example of reference pattern services 8-1
  - example using window services 4-6
- call statements for latch manager services 9-1
- call statements for reference pattern services 7-1, 8-1
- call statements for window services 3-1, 4-1
- call syntax
  - for latch manager service 9-1
- changed data in an object
  - refreshing 2-9
- COBOL programming language
  - call syntax for latch manager services 9-1
  - example using reference pattern services 8-4
  - example using window services 4-9
- commit changes to protected resources 10-9
- commit protocol, two-phase 10-2
- CSREVIEW callable service
  - defining a view of an object 2-4
  - parameter descriptions 3-2, 3-18
  - purpose 3-1, 3-17
  - return codes and reason codes 3-4, 3-20
  - syntax 3-2, 3-18
- CSRIDAC callable service
  - obtaining access to a data object 2-2
  - parameter descriptions 3-6
  - purpose 3-5
  - return codes and reason codes 3-8

- CSRIDAC callable service (*continued*)
  - syntax 3-6
  - terminating access to an object 2-12
- CSRIRP callable service
  - example 6-5
  - purpose 7-1
- CSRIRR callable service
  - purpose 7-3
- CSRL16J callable service
  - entry characteristics for the target routine 12-1
  - freeing dynamic storage for the target routine 12-2
  - parameter description 12-1
  - programming requirements 12-2
  - return codes 12-6
  - syntax 12-1
- CSRREFR callable service
  - parameter descriptions 3-10
  - purpose 3-10
  - refreshing changed data 2-9
  - return codes and reason codes 3-11
  - syntax 3-10
- CSRSAVE callable service
  - parameter descriptions 3-13
  - purpose 3-12
  - return codes and reason codes 3-13
  - syntax 3-12
  - updating a permanent object on DASD 2-10
- CSRSCOT callable service
  - parameter descriptions 3-15
  - purpose 3-15
  - return codes and reason codes 3-16
  - saving interim changes in a scroll area 2-8
  - syntax 3-15
  - updating a temporary object 2-8
- CSRSIC include file 13-4
- CSRVIEW callable service
  - defining a view of an object 2-4
  - terminating a view of an object 2-10

## D

- DASD (direct access storage device)
  - data transfer from by window services 1-3
  - updating a permanent object 2-9
- data-in-virtual object 1-1
- data object
  - define multiple views 2-7
  - defining a view 2-4
  - extending the size 2-7
  - identifying 2-2
  - mapping 1-1
    - DASD to a scroll area 1-3
    - DASD to a window 1-3
    - multiple objects 1-5
    - object to multiple windows 1-4
    - scroll area to a window 1-3
    - temporary object 1-4
  - obtaining 2-1

data object (*continued*)  
    access to a data object 2-1  
    scroll area 2-3  
    obtaining access 2-2  
    refreshing changed data 2-9  
    saving an interim change 2-8  
    specifying type of access 2-3  
    structure 1-1  
    terminating access to an object 2-12  
    updating a temporary object 2-8  
data to be viewed  
    identifying 2-6  
DFP requirement for window services 2-3  
direct access storage device 1-3

## E

examples  
    data object mapped to a window 1-2  
    mapping 1-3  
        multiple objects 1-5  
    object to multiple windows 1-4  
    permanent object that has a scroll area 1-3  
    permanent object that has no scroll area 1-3  
    temporary object 1-4  
    structure of a data object 1-2

## F
